NOTES AND COMMENTS.

What is Whiskey?

No judgment has been given by the Newington Sessions on the appeal against the magistrate's decision upon the question as to what constitutes Scotch and Irish whiskey. The justices were equally divided upon the point, so that the original position is maintained. Unless the appellants decide to bring the matter before the Sessions for re-hearing, the law will be laid down that it is unlawful to sell patent still spirit, pure or blended, in place of Scotch or Irish whiskey made from the old-fashioned and, as we believe, the more wholesome pot still.

Hospitalism.

WRITING to the *Times*, a correspondent of June 24th has entered a vigorous protest against the pauperising influences of medical charity, or, as he calls it, "hospitalism." He insists upon the disastrous fact that two-thirds of the population of London are habitual recipients of medical relief from voluntary or State-aided institutions. He is confident that two-thirds of the persons who die in London (infants excepted) have been treated gratuitously for the illness of which they die. His figures are truly Gargantuan. Besides the 40,000 patients who occupy the beds of the metropolitan charities, there is a free daily attendance of over 20,000 persons in addition at Poor-law stations, while the Sunday Fund registers over six million attendances at institutions on its list. The writer of the letter asserts that "the out-patient and casualty departments of the London hospitals are a disgrace to any community."

Panem et Circenses.

HE then goes on to attack what he calls a new scheme for adding to the pauperisation of the people. The object of his caustic comments is the fund under H.R.H. Princess Christian to provide spectacles for elementary school children at wholesale prices or less. He points out that nickel steel spectacles can be fitted at 1s. 1d. to 1s. 9d. per pair, and at lower prices still with blue steel rims. His contention is that parents who can afford to spend £5 to £10 a year on drink should not need a special Royal Fund to enable them to pay two or three shillings for spectacles. Most medical men will probably agree more or less cordially with that proposition, as well as with the wider argument in favour of curtailing the indiscriminate charity of the hospitals. Free spectacles are bad for opticians, just as free medical advice is bad for the general practitioner. Still, we cannot fully agree with the writer as to the danger of "hospitalism" to the country. "The popular clamour for *panem et circenses*," he perorates "heralded the fall of Rome; our modern equivalent is free education, free medicine, free meals, free pensions, and now free spectacles."

Herbalists and Death Certificates.

ONE of the most striking facts about the modern charlatan is his brazen assurance. No better illustration of this quality could be given than the demand on behalf of the members of a certain herbalists' college at Southport to grant certificates of death. The "College" claims to be "a school of non-poisonous herbal medicine, vitalian and personal hygiene." Last year it was flouted by the refusal of the local Registrar of Births and Deaths to accept a death certificate signed by one of its collegiates. In response it has formed a "People's League of Medical Freedom," which has adopted as its war-cry the claim "That any herbal or other practitioner be able to give a death certificate equally with allopathically-trained practitioners, so long as those who employ them are satisfied." Their manifesto asserts that the inalienable right of every Englishman to choose his own doctor is being threatened by the medical profession, who "are seeking parliamentary aid to suppress everyone but themselves," and that the only alternative to this injustice will be "when sick, to suffer and die without anybody's help or aid." Why do not these zealous guardians of freedom usurp the lawyer's profession on the ground that every man has an absolute right to choose his own lawyer? The man in the street, however, is apt in nine cases out of ten to believe in his own powers as a physician, whereas he is in doubt when it comes to a point of law.

At Last.

AT length a member of that strange sect, the "Peculiar People," has been brought to book and properly punished. A carman, named James Cook, belonging to that eccentric faith, was last week found guilty of the manslaughter of his children, Dorothy May, aged six years and nine months, and Hilda, eighteen months, by neglecting to summon medical aid during sickness. Cook had been previously convicted for manslaughter under similar circumstances, but was discharged with a caution. This time he has been sent to prison for nine months, with hard labour. It is to be

hoped that this salutary sentence will afford Cook time to ponder over the responsibility accepted by other folk with regard to the care of their children in sickness, a duty that the "Peculiars" complaisantly shift on to the shoulders of Providence. Fatalism of this kind constitutes a species of moral insanity, and those who are under its influence should be dealt with as mentally irresponsible persons. Clearly it is the duty of the State to protect the lives of its subjects, and the question arises whether the Peculiar People should be allowed to keep children in their power.

The Christian Science Trial.

THE trial of Dr. Adcock at the Old Bailey last week for manslaughter has come to an eminently unsatisfactory conclusion. The jury disagreed, and the case stands over until the next session. Under these circumstances, we are compelled to refrain from comment upon the death of Major Whyte while under the care of the accused, who has embraced the tenets of a curious sect who call themselves "Christian Scientists." For our own part, we see little or no difference between culpable neglect in providing medical attention if practised by a wealthy Christian Scientist or a poverty-stricken Peculiar People. The latter are now punished for deaths arising from culpable neglect to procure medical aid. Both sects claim to have divine authority for the rejection of that particular kind of human help. Surely, both bodies should be equally accountable to the law for the result of their criminal foolishness. In the case of Dr. Adcock, the matter is complicated by the fact that he is possessed of medical training and experience. It is high time that the exact legal position and responsibilities of Christian Scientists were authoritatively settled in the Law Courts. Just before going to press we learn that the judge has formally stated to the prosecution that in his opinion there was not sufficient evidence to prove guilt. The prosecution, therefore, may be abandoned.

LEADING ARTICLE.

THE REDEMPTION OF THE INEBRIATE—THE DEGRADATION OF THE *TIMES*.

WE regret to note that another of the series of puffs of the "Keeley Institute," headed "The Redemption of the Inebriate," upon which we commented in a leading article on May 23rd, was published in the *Times* of Wednesday last. In our article we clearly showed how disgraceful and slanderous were the imputations upon our profession conveyed in the puffs, and we gave besides more than sufficient reasons why they ought never to have been admitted in such a form, bearing the endorsement of the leading journal. We have little doubt these advertisements, in spite of their high price, will prove exceedingly profitable to the "Keeley Institute," but we have no doubt at all that however much the *Times* may find itself in pocket over the transaction the gain will in the end be many times outweighed by the injury inflicted upon the reputation of the paper. Up to late years the *Times* has indisputably claimed in every respect the title of leading journal—leading not only among British newspapers, but among those of the whole world—and its superiority has nowhere been more conspicuously displayed than in its advertising columns. Puffs, even of a harmless kind, printed so as to lead the ingenuous reader to take them for editorials, have been until recently undiscoverable in its pages; and it is questionable whether in former years the Keeley puffs would have been accepted even in the form of ordinary advertisements. The *Times* has hitherto always acknowledged and acted upon the fact that there is little difficulty in recognising medical pretenders of any kind, and has given proof of its motives by refusing certain classes of advertisements which have always found a place in other newspapers. The *Times*, in its editorial utterances has especially pointed out and dwelt upon the fact that "the whole enormous system of quack advertisements is conducted on the lines of implied disparagement of doctors," and yet the managers, who can hardly disclaim acquaintance with our statements, are now not ashamed knowingly to publish a series of puffs of the character we have exposed. We repeat it will not pay them in any sense of the word. Medical readers—and they number many thousands in every civilised land—men of science, and men of the world, will be indignant and disgusted to find the fountain of journalistic honour thus befouled for the sake of filthy lucre. Those the gods wish to destroy they first make mad; and we do not doubt that the present amazing business methods of the *Times* if persevered in will end in the destruction of all those things its founders and earlier conductors set most value on. The degradation of the *Times* will surely lead to further degradation of all that is at present inferior in the world of journalism. All this must form a source of deep regret to everyone who realises how great a power for good the *Times* in the past has been, and how much mightier a power it could have in time become had the old methods been continued by which it was once conducted and by which its well-deserved fame was established.

THE annual dinner of the Fellows of the Royal College of Surgeons of England will take place tomorrow (Thursday) evening. Fellows intending to be present who have not yet communicated with the honorary secretaries of the dinner committee at the College are requested to do so at once in order to facilitate the necessary arrangements as to numbers.

MR. JOSHUA PEDLEY has promised to provide one-third of the sum of £1,400 still required for the rebuilding of the Tottenham and Edmonton Dispensary premises conditional upon the committee finding the other two-thirds.

THE death is announced of Signor Garcia, the inventor of the laryngoscope, and a famous teacher of singing, at the ripe age of 101. When he was about 70 he married for a second time, two daughters being issue of the marriage. He did not touch wine or spirits until he was ninety and was still giving lessons to pupils at 96.

NOTES ON CURRENT TOPICS.

Prevention of Infantile Mortality.

IT is some satisfaction that at length the public conscience has been a little roused on the subject of infant mortality. In season and out of season, medical men have drawn attention to the scandalous havoc wrought among young children by ignorance and carelessness, but up to the present they have been as a voice crying in the wilderness. It does not follow, moreover, that with the awakening of the public conscience there will be a corresponding improvement of the public health, since there is much reason to fear that unless great care be taken the remedies adopted may be all but as bad as the disease. Assuredly, no case requires more careful or prudent consideration. Well-meaning people—and the well-meaning are often more dangerous than the ill-disposed—recognising, for instance, that it is difficult to procure pure milk for infants, are sure to jump to the conclusion that all that is necessary is to supply good milk to every home, with instructions as to its preparation for infants. They forget, however, that cow's milk, however pure and fresh, is at best a poor substitute for the milk by a healthy mother. Again, a wholesale establishment of *crech* s for the children of working women has been urged, forgetting that *crèche* —useful as they are—may very easily be allowed to sap the parental responsibility, which is the foundation of family life. They may, too, encourage the too early return of a woman to work after her confinement. The only improvement we can hope for in the health of infants must be through the mothers, and without educated, careful, and healthy mothers we shall not have healthy children. Any plan, therefore, which ignores the condition of the mothers will only lead to a worse state than exists at present.

The Whiskey Problem.

THE terse question, "What is whiskey?" remains unanswered by the Appeal Court. The legal proceedings that have attended the prosecution and subsequent appeal have cost a great deal of money, but have brought no peace to the perturbed mind of the man in the street. If he asks for whiskey at a bar is he entitled to have spirit made from the original pot still or "silent" spirit from the modern substitute, the patent still? Alas, for all who indulge in whiskey, the magistrates say that they must have pot still spirit, but the final authoritative decision of the higher court is not yet given, perhaps never will be forthcoming. It may be that sufficient guidance on the point may be secured from the fact that the principal distillers in England, Ireland and Scotland insist that pot still whiskey is the original and best article, a view we have all along supported in these columns. In any case it seems to us that a man is entitled to know what he is buying. Patent still whiskey is far cheaper than the pot still product. That fact cannot be gainsaid by the most ardent supporter of the patent still. Under these circumstances the course pursued by Messrs. W. and A. Gilbey appears to be straightforward and sensible. They sum up the matter in the following nutshell:—"If a customer desires Scotch or Irish whiskey he should not be served with a cheap substitute on the plea that it is good for him. If, on the other hand, he is content to accept the cheaper article, he should not be charged a high price for it on the assumption that it is 'fine old Scotch or Irish whiskey.'" Messrs. Gilbey, therefore, have adopted the simple plan of selling both kinds under labels stating whether the bottle contains pure malt pot still whiskey or pot still blended with patent still spirit. This solution of the difficulty reminds us somewhat of the downright tactics of the warrior who cut the Gordian knot he could not unravel.

Why Go To Foreign Spas?

THE fires of patriotism illumine with fierce light many topics connected with trade and agriculture. Numerous other things of equal importance, however, they leave alone in the shades of cold obscurity. Take the case of the spas and watering-places of England, Scotland, Ireland and Wales. There is hardly a known medicinal virtue, whether of earth, sky or sea, or of the waters beneath the earth, that cannot be obtained in some part or other of the United Kingdom. A moment's reflection will show this to be the case when one recalls the fame of Bath, Harrogate, Tunbridge Wells, Matlock, Woodhall Spa, Llandrindod Wells, Strathpeffer, and many other equally noted mineral springs in Ireland, Scotland and Wales. The seaside resorts of the United Kingdom, again, offer every possible variety of attraction as regards climate and other health-giving conditions, not to mention fairy-land beauties of sea and shore. The Balneological Society of Great Britain has done a great deal to draw attention to our neglected health resorts. It would be well were the spirit of domestic patriotism diffused more widely among the medical practitioners and the laity of the United Kingdom, so far as spas and other health resorts are concerned.

The Most Insanitary District in the Kingdom

THE exposure of the sanitary circumstances and administration of the urban district of Merthyr Tydvil made in the just-issued report of Dr. J. Spencer Low, of the Local Government Board, would no doubt astonish the public if only they could be induced to pay any attention to it; but it is not likely to surprise any one sufficiently acquainted with the defects of sanitary administration as it is conducted by a great proportion of the local authorities throughout the country. Merthyr Tydvil has perhaps gained the unquestionable right to the title of the most insanitary district in the kingdom, but there are a whole crowd of places—urban and rural—whose claims to a similar distinction are not much less weighty

Almost every single defect injurious to the public health has existed in Merthyr Tydvil for many years. They have been reported on over and over again by the Medical Officer of Health, and even by sub-committees of the Council, but no action has been taken upon the reports. It is no wonder that Dr. Low declares it to be obvious that there has been an obstructive element in the Council sufficient to shelve for a number of years the remedying of evils which have been yearly pointed out in a most insistent manner by successive medical officers of health. We need not now analyse the death-rate of the town; our main object is once more to emphasise the fact upon which we have often insisted that the blame for the shocking disregard of duty displayed by too many local authorities rests upon the general public. Local authorities are what the citizens and ratepayers choose to make them. The remedy, and the only complete remedy for existing abuses is to turn out inferior members of governing bodies and replace them by men incapable of sacrificing the welfare of their fellow citizens through ignorance, if not in pursuit of sordid and selfish ends. There exists in these islands very little of the municipal corruption such as disgraces the United States, but the prevailing apathy, the lack of local patriotism, the disinclination of the wealthier classes to make any personal sacrifice for the good of the community, constitute a danger to the State.

Immunisation against Tuberculosis.

RECENT investigations demonstrate the possibility of protecting young calves against tuberculosis by the administration in food of bacilli that have been killed by boiling or other application of heat. The results have been confirmed by several trustworthy authorities and only two points remain to be cleared up for the method to be applied on a large scale, viz., the duration of the immunity thus procured and the possibility of obtaining similar results in human beings. Certainly a means of immunisation would have a great future that is devoid of risk in a form that admits of being taken by the mouth, thus avoiding the risks inseparable from subcutaneous injections. Now, milk is the only food likely to contain tubercle bacilli that is consumed raw, and the importance of boiling it as a routine prophylactic measure is emphasised by the fact that the milk of tuberculous cows, especially those suffering from tuberculous lesions of the udder, becomes, by boiling, an immunising agent of the first order, indeed the richer the raw milk in bacilli the more active its protective properties when boiled. It may be well that in the near future milk will be deliberately "guaranteed rich in bacilli," and cows will be injected with tuberculin in order to select animals proved to have the disease. The idea is gaining ground that the air passages are, after all, not the ordinary channel of tuberculous infection, since numerous experiments have shown with what facility tubercle bacilli, when administered with food, find their way into their happy hunting ground, the lungs. Should this supposition prove to be correct, it would by no means invalidate the necessity of preventing the dissemination of the tubercle bacillus in the form of dust; for whether swallowed or inhaled the results are in the highest degree dangerous. It is infinitely probable that the bacillus selects the path of least resistance, and while in the very young this appears to be *via* the digestive tract, in older persons the lungs are likely not only to be more accessible, but also more vulnerable.

The Public Health of Belfast.

DURING the past few weeks a hot controversy has raged in Belfast over the appointment of a Medical Officer of Health to succeed Dr. Whittaker, who has recently resigned. The medical profession and the newspapers generally have strongly urged the appointment of a specially trained medical man, experienced in public health work, to whom an adequate salary should be paid. A deputation from the Ulster Medical Society, which recently waited on the Corporation, drew attention to the fact that the death-rate in Belfast is extremely high, and that up to the present there has been no adequate sanitary department. The Public Health Committee, while denying that the health of the city is in an unsatisfactory condition, recommended that a salary of £800 a year should be attached to the office of Medical Officer of Health. The Corporation has decided, however, that £600 is sufficient, and it is rumoured that this decision is intended to limit the number of expert candidates in order to give the post to a gentleman recently a member of the Corporation. It is hardly credible that in a prosperous and progressive city like Belfast such an important decision as is here involved should be influenced by improper motives. Cardiff and Leeds each pay their medical officers £800 a year, and give him trained assistance. Liverpool pays £2.500 in salaries to the medical officer of health and his assistants, and Manchester a nearly equal sum. These are the cities with which Belfast should compare itself, and we trust it is not yet too late to admit of suitable arrangements being made for the care of the lives of its citizens.

Population and Emigration.

THE report of the Departmental Committee on Emigration appointed about a year ago by Mr. Lyttelton, then Secretary for the Colonies, has just been published. The report brings into prominence and emphasises the fact upon which we dwelt in an article a week or two ago upon the conference on Infantile Mortality—the fact, namely, that the efforts of statesmanship ought to be first of all directed to removal of the true prime causes of degeneracy. If the bulk of our increase were composed of men and women physically, mentally and morally fit there could be no difficulty in providing for them. All our

Colonies are crying out for population ; they are ready to absorb all our surplus people, but object to receive them in the form of wastrels, degenerates and unemployables. The problem at home is thus to prevent the breeding and rearing of these classes. This is to a large extent to be accomplished by application of the sanitary laws which have been placed upon the Statute book within late years, but which in most localities are not properly administered. The mortality among infants is, as we have so often insisted, an index of the amount of degeneracy among the survivors. The main factors in the causation of the mortality are well known, and being preventable, ought to be prevented. The Poor-law, as at present administered, tends to the creation of chronic pauperism, and this is especially true of the vagrancy problem. Professional tramps and vagabonds of all classes drag about with them thousands of children who are moulded into a form which unfits them for any but a life of idleness and crime. It seems a pity that Parliament cannot take in hand the details of these phases of the social problem, and apply the obvious remedies. The report of the Vagrancy Committee has been out for some months ; perhaps when the Royal Commission on the Poor-law, which is still sitting, shall in turn have issued its report the subject may receive the attention it so urgently calls for from the Legislature.

The Tinned Meat Scare.

IT is to be hoped that the public will learn some useful lessons from the revelations which have been made concerning the conditions under which potted meat is prepared in Chicago. Already there is a natural, though somewhat illogical revulsion of taste from imported to home-prepared preserved meats, it being assumed that the English factories are managed in a perfectly satisfactory manner. Though it is likely that at least some of the Chicago horrors are unknown in this country, yet if this be so it is in no way due to the precautions imposed by the community, but rather to the different business habits of our manufacturers. As a matter of fact, the inspection of meat factories is not of such a nature as to ensure that only sound meat is used. The inspection of imported meat is of necessity still more unsatisfactory. It is impossible, in the great majority of instances, to tell without opening a tin, whether the contents are putrefied or not, and the examination of every tin is an impossibility. Moreover, the dangers to be feared are not always those arising from the presence of bacteria or the ptomaines produced by them. It not infrequently happens that tin or lead is present in appreciable quantity in the contents, though its presence is not likely to be discovered or even suspected without chemical examination. It would seem that it is impossible to ensure a perfectly safe supply of imported tinned meats, so that it is all the more necessary that the home-prepared material should be above suspicion.

PERSONAL.

DR. F. B. CROSBY, who was last week elected one of the Sheriffs of the City of London, is in active practice as a physician. He entered the Common Council in 1877, and was elected Alderman in 1898.

THE honour of Knighthood has been conferred upon Professor A. E. Wright. From 1892 to 1902 he was Professor of Pathology at the Netley Army Medical School, and was a member of the Indian Plague Commission, 1898 to 1900. He has done much scientific work, and in 1897 was appointed Pathologist at St. Mary's Hospital.

DR. ROBERT FARQUHARSON, whom His Majesty has created a Privy Councillor, is well known as the medical officer to Rugby School, assistant physician to St. Mary's Hospital, and lecturer on materia medica. His chief work is the well-known "Guide to Therapeutics."

SIR CHRISTOPHER NIXON, whom the King has created a baronet, is a distinguished Irish physician, who has been president of the Royal College of Physicians in Ireland, as well as of the Royal Veterinary College in that country.

AMONG the Birthday honours bestowed by His Majesty, few are more deserved than the Knighthood conferred upon Professor Alexander Russell Simpson, M.D.,D.Sc., who was born in 1835. He was from 1870 till 1905 Dean of the Faculty of Medicine and Professor of Midwifery and Diseases of Women and Children at Edinburgh University. The baronetcy of his uncle, the famous Sir James Simpson, is now held by a cousin of Sir Alexander Simpson.

DR. E. M. WILKINS has won the annual challenge cup of the Manchester and District Medical Golfers' Association.

PROFESSOR H. S. F. GRUNBAUM has been elected Dean of the Faculty of Medicine and Chairman of the Board of the Medical Faculty of the University of Leeds in place of Professor de Burgh Birch, who has resigned.

THE coming retirement is announced of Mr. F. T. BUCHAN from the position of Poor Law Inspector of the Local Government Board for Wales and Monmouthshire.

THE Raymond Horton-Smith prize for the best M.D. Thesis in the University of Cambridge has been awarded to Harold Theodore Thompson, M.D., B.C., of Christ's College, "On Certain Changes in Sensation associated with Gross Lesions of the Spinal Cord."

DR. FREDERICK TURNER, J.P., medical officer of health at Buxton, has resigned his post, which he has held for thirty years.

WE regret to announce that Dr. Robert Craik, who was for many years Dean of the Medical Faculty of McGill University, died last week at Montreal at the age of 77.

PROF. T. GREGOR BRODIE, F.R.S., is announced to give a course of five lectures at the "Brown" Animal Sanitary Institution (University of London) during the present month ; the dates and subject of which will be found on reference to our advertising columns.

SIR CONSTANTINE HOLMAN has resigned his position of treasurer of Epsom College, which he had occupied for nineteen years. Fifty-one years ago he took part in the initiation of the College. In 1887. when he became treasurer, there were 191 pupils, as compared with 254 now.

A CLINICAL LECTURE
ON THE
VALUE OF PHILIPOWICZ'S AND BERNARD'S SIGNS IN THE DIAGNOSIS OF TYPHOID FEVER.

By Professor LOUIS REGIS, M.D., of the Faculty of Medicine of Paris.
[Specially reported for this Journal.]

A CASE of typhoid fever with pneumonic complications in a child, æt. 4, affords me an opportunity of discussing with you the clinical value of two clinical phenomena which so far have been very inadequately studied in this country, and to which in any case too little importance is at present paid. The young patient, aged four years was brought to me by his mother on September 5th, 1904. She informed me that the little man had just returned to Paris after passing three weeks in the country, where he had enjoyed the best of health until he was on the point of undertaking the return journey. Just at that time he complained of feeling tired, he lost his appetite, he coughed, had diarrhœa with slight fever, and passed very restless nights.

The child's flushed face, his unequally coloured cheeks, and a rather marked shortness of breath made me at first suspect a pulmonary affection. I auscultated him, and on the right side I discovered the existence of a typical pneumonia with its ordinary clinical associations. Continuing my examination, I noticed that the spleen was somewhat enlarged and sensitive to pressure, and that there was gurgling in the right iliac fossa. Lastly, the palms of the hands presented a distinct yellowish coloration. The rectal temperature was 40° C. (104° F.).

Although, it is true, the pneumonia that I had discovered might *a la rigueur* suffice to explain the whole symptomatology, including the abdominal signs, the more so seeing that the little patient, whom I had already attended for measles, gastro-enteritis, and membranous enterocolitis, was very subject to intestinal disturbances, the state of the stomach and especially the yellowish coloration of the palms forthwith suggested to me the possibility of typhoid infection.

I therefore postponed any diagnosis until the following day. I ordered a mild purgation and hot moist applications with, every three hours, a mixture containing acetate of ammonia, enjoining at the same time a milk diet. On the following day I made a fresh examination. The palms of the hands and the soles of the feet exhibited a well-marked yellow coloration almost like that of jaundice (Philipowicz's sign), and on deep palpation of the ileo-cæcal region I discovered two swellings which gave the sensation of movable glands, the size of a filbert (Bernard's sign).

The family were not in affluent circumstances, so that we could not instal a bath; moreover, the patient could not be properly isolated, so having diagnosed typhoid fever I advised them to have the child removed to the nearest hospital. The child was admitted on account of the pneumonia, the mother's assurance of the existence of typhoid fever to the contrary notwithstanding. It was only on the fourth day after his admission that the disease was identified as typhoid, and that the usual treatment was instituted. The disease ran its course in about six weeks, and I ascertained subsequently that the belated diagnosis was based on the sero-reaction.

Here, then, gentlemen, was an unquestionable case of typhoid fever which presented all the clinical appearances of an attack of pneumonia, but which I had been enabled to diagnose without the assistance of any of the many ingenious laboratory reactions, that is to say, I had suspected it on the fifth day and had confirmed my suspicion on the sixth. If I insist on the dates it is in order the better to emphasise the very great value of these two signs which I will now proceed to discuss in detail, epitomising the researches and criticisms of which they have been the object during the last few years.

In 1903, Philipowicz, in the course of an epidemic of typhoid fever at Odessa, noticed that all his patients presented a more or less well-marked yellow coloration of the palms of the hands and the soles of the feet. This coloration, which persisted in spite of washing and scrubbing, was most pronounced on the prominent parts, the thenar and hypothenar eminences, the finger tips, the heel and the internal and external plantar region. Moreover, the callosity of the hands and feet seemed to reinforce the colour, turning it to orange and even to saffron yellow. Lastly, the colour faded aud disappeared as recovery took place.

For a long time Philipowicz made comparative observations of the hands of his typhoid patients and those of his other patients suffering from various affections, and he found that the coloration was peculiar to enteric patients. After nine years of patient research and comparison he published a detailed description of the "palmo-plantar sign," a descriptive title which, in conformity with the objectionable practice of naming things after the names of their discoverers, is now known as "Philipowicz's sign."

The pathogenesis of this sign is still quite obscure. Philipowicz believed it to be due to the intoxication of the organism by the toxins of the bacillus of Eberth. According to him these toxins modify the circulation, consequent upon changes in cardiac activity, and so bring about a slowing down of the circulation in the cutaneous capillary system. He based this belief on the dicrotism of the pulse, the frequent disproportion between the pulse-rate and the temperature, the pallor of typhoid patients, and the dryness of the skin. This diminution of the blood in the cutaneous capillaries may very well be dependent upon the hyperæmia of the mesentery, the spleen and other organs in the abdomen. The palms of the hands and the soles of the feet, receiving an inadequate supply of blood, undergo a degree of atrophy and allow the yellow colour of the subcutaneous layer of fat to show through this layer, being especially abundant in the prominent parts of these regions.

This explanation is not admitted by most authors who have studied the subject. Motta Coco and Quintin attribute the phenomenon to a simple local inflammatory process or to the local action of the typhoid toxins, while Gilbert and Hercher explain it in accordance with their own views of hæmapheism.

Philipowicz attaches a pathognomonic diagnostic value to this sign as well as a prognostic value, the severity of the attack being, according to him, in proportion to the intensity and the precocity of the coloration.

This symptom has been the object of much critical study in Italy, more particularly by Baccarini, Querola, Lacchesini, and Motta Coco, whose remarkable monograph on the subject terminates with the following generally admitted conclusions :—

(1) The palmo-plantar sign is almost invariably present in enteric patients. It is most constant in children, then in women, and, lastly, in men. (2) The palmo-plantar sign usually makes its appearance during the first seven days, more rarely in the course of the second week. It disappears when convalescence sets in, but promptly reappears in the event of a relapse. (3) The palmo-plantar sign possesses great importance in the diagnosis of typhoid fever without, however, being entitled to be regarded as pathognomonic. It has no prognostic value. It may be present or absent, be well-marked or very slight, in mild as well as in grave cases.

From these data you will gather that this palmo-plantar sign, so readily discoverable, possesses a well-nigh pathognomonic significance when its presence is associated with certain other early signs of typhoid fever.

Peculiár to infancy, the second symptom, much more recently discovered, is even less well-known among us. The credit of its discovery belongs to Dr. J. Bernard, of Zychyfalva, in Austria, who first described it in 1902. To find it we must carefully and methodically palpate the right iliac fossa, especially in the ileo-cæcal region. In a typhoid patient we shall feel two or three small swellings varying in size from a filbert to an almond. These tumefactions lie parallel to the longitudinal axis of the colon at a distance of from half to one inch from each other. They do not become perceptible until the end of the first week, and usually disappear some days later.

The presence of these tumours has been attributed to hypertrophy of Peyer's patches and inflammation of the mesenteric glands. This last hypothesis seems quite inadmissible, by reason of the anatomical situation of the mesenteric glands, which, when enlarged, would be felt to lie horizontally, whereas the enlargements in question are more vertical. Peyer's patches may all the more plausibly be incriminated, seeing that the size of the swellings corresponds thereto, and that they are parallel to the axis of the intestines, especially if we bear in mind that the anatomo-pathological process in the young is hyperplasic in contrast with the necrobiotic tendencies of typhoid fever in the adult.

This, gentlemen, completes my description of these two signs. With regard to the palmo-plantar sign, in view of its almost invariable appearance at the very onset of the disease, and the ease with which it can be ascertained, one cannot but experience a feeling of surprise that it should not already have acquired a more prominent place in typhoid symptomatology. It will, I am convinced, assist you greatly in your future career in the diagnosis of a disease which always comes upon us more or less as a surprise and with regard to which we cannot have too many means of control.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The Lecture for next week's issue will be by Charles Barrett Lockwood, F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, London, President of the Harveian Society, "On Carcinoma." Lecture delivered at St. Bartholomew's Hospital, May 23rd, 1906.*

ORIGINAL PAPERS.

SOME EXAMPLES OF CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.*

By GEORGE CARPENTER, M.D.Lond.,

Physician to the North Eastern Hospital for Children, Membre Correspondant de la Société de Pediatrie de Paris.

THE following cases are narrated as a contribution to the study of congenital stenosis of the pylorus.

This uncommon condition has of recent years received a good deal of attention at the hands of various writers, and from time to time isolated examples of the complaint together with more elaborate communications have been recorded in medical journals at home and abroad. But the condition is a rare one, for there are many children's physicians in large practice and with an extensive experience of children's ailments who have never met with a case. Moreover, cases that appeared to possess all the symptoms and local characteristics of the disorder have been published from time to time, and who have apparently completely recovered from the complaint by judicious feeding and by medical measures. But such cannot be considered above suspicion, for there are many opportunities of falling into error and being deceived. On the other hand, pathological specimens removed from the bodies of those presumed to be suffering from the complaint have not always appeared to us to warrant such a diagnosis from their morbid appearance. There can be no question, however, as to the correct diagnosis of my cases, for they were in each instance verified by surgical procedures, and unfortunately confirmed by *post mortem* examination.

Edward J——, æt. 3 weeks, was sent by Dr. Douglas Wright to Dr. George Carpenter and was admitted into the North Eastern Hospital for Children on June 8th, 1905. The child was full term and the sixth pregnancy. There had been neither miscarriages nor still births. The weight at birth was 8¾ lbs. It started vomiting on June 1st, when a fortnight old ; since then it had been sick after almost every feed. Occasionally three feeds were passed by without sickness, but then it vomited a large quantity. Specks of blood were noticed in the vomit, but the mother had a sore nipple. At times the vomit was brown, like beef tea. The bowels were natural until the commencement of the vomiting, when they became costive. Soap enemata were followed by a small bright green stool. The last motion was sage green in colour and of a uniform tarry consistency.

On admission.—A hard tumour the size of h e terminal phalanx of the little finger was found deep down in the abdominal cavity above and to the left of the umbilicus. The infant was weighed on June 12th and found to be 6¼ lbs., a loss of 2¼ lbs. since its birth. Since its admission it had vomited from 5 to 8 times in the 24 hours. It was given a mixture

* Pathological specimens exhibited at the Society for the Study of Disease in Children, October 20th, 1905, and January 19th, 1906.

of milk and barley water by the mouth, 1¼ ozs. at a time.

June 15th. Since admission the bowels have acted irregularly—on three days once or twice in the 24 hours and of a dark green colour, at others not at all. Vomiting as before. The temperature has been subnormal On June 17th, visible peristalsis was first noticed. The child's eyes looked sunken and it was obviously

FIG. 1.

wasting. The temperature ran up to 101·2° F. Nutrient enemata were ordered. The stools were a little more frequent; the sickness as before. On June 19th, Mr. Ewen Stabb saw the patient with Dr. Carpenter and it was decided that the pylorus, which felt as hard as iron, should be freely dilated. The stomach was opened by a longitudinal incision. The stricture would just admit a No. 4 gum elastic catheter. The pylorus was dilated by a pair of blunt ended dressing forceps. When the dilating was finished the little finger could be passed through the pylorus with ease. A soft catheter was pushed into the duodenum and a feed of milk and brandy administered. The stomach was sewn up with Lembert's sutures. Owing to the stony hardness of the tumour pyloroplasty was thought impossible of performance and the simplest operation selected in view of the child's critical condition. The child was collapsed afterwards. The temperature at this time was normal. On June 20th, mouth feeding was stopped owing to sickness which occurred after and between the feeds. Albumen water was given by the mouth a teaspoonful every half hour. June 21st, albumen water and about half the rectal feeds retained. Temperature raised since the operation this evening to 102°F. June 22nd, Wound dressed. The infant is becoming more wasted and the eyes more sunken. Taking milk and barley water by the mouth. Since the operation has vomited from 2-4 times in the 24 hours and the bowels have been opened from 2 to 4 times. Temperature 103·5°F. June 27th. He had lost 1¼ lbs. in weight. Vomiting occurred but once on this date, once on the 26th, not at all on the 25th, but 4 or 5 times on the 23rd and 24th. The bowels were opened from 3 to 5 times in the 24 hours, loose and black stools. The temperature was about 100°F. Mr. Sydney Stephenson was asked to examine the infant's eyes and reported that there was a septic ulcer taking up two thirds of the right cornea, with protrusion of Descmet's membrane. On July 2nd, the ulcer perforated and the lens was found under the upper lid. In the meanwhile the child had been sick from 2 to 3 times in the 24 hours and the bowels had been opened from 4 to 11 times. The temperature had been subnormal with one or two exceptions when it rose to 100°F. He died on July 4th, the *post mortem* examination was made on July 5th. The wound had not healed. The infant was greatly emaciated. All the organs were normal. The pylorus was as described on physical examination. On filling the stomach with water none passed through the pyloric opening. The stomach held 4 ozs., the whole of the intestines were collapsed. The right eye was completely disorganised from suppuration. The child evidently died of starvation.

CASE 2.—Annie D——, æt. 5 weeks, the first infant, was a fine child at birth. She was fed on the breast and had occasional attacks of sickness. When a fortnight old she was put on the bottle. When 3 weeks old she had wasted "a good deal." Proprietary foods were then tried and later sterilised milk, but nothing seemed to suit her. By the fourth week she was much worse and either vomited every feed or accumulated feeds in the stomach and then "pumped them on the floor." She was always constipated. She was admitted into the North Eastern Hospital on July 10th and looked somewhat wasted but she weighed 7¼ lbs. A lump was felt in the region of the pylorus. Under an anæsthetic, which the child took badly, the lump was found to be of cartilaginous hardness and it was grooved transversely. It was thought to be about the size of the terminal phalanx of the index finger and the stomach walls in its neighbourhood also felt thickened. The intestine (duodenum) also was thought to be somewhat thickened. After the examination the infant was fed by nutrient enemata. Water was given by the mouth and 10 minims of brandy hourly, as it had a very poor pulse. It was sick 4 times. On the morning of July 11th, just before the operation, the pulse was weak and the child was somewhat cold. A hypodermic injection of brandy was given. Ether was administered. Mr. Lockhart Mummery operated and the appearance of the pylorus tallied with the description already given. The growth

FIG. 2.

FIG. 3.

was of cartilaginous hardness and the thickening extended chiefly along the greater curvature of the stomach but also along the lesser. Mr. Mummery deemed it impossible to perform pyloroplasty and anterior gastro-enterostomy was done, the operation taking 25 minutes to perform. The infant was returned

from the theatre in a collapsed state and very soon afterwards it started continuous vomiting of blood, not in any great quantity at a time, but it lost a good deal in small amounts. A solution of adrenalin (Adrenalin solution 1 drachm, normal saline solution 5 drachms, standing on ice); minims 10 every hour by the mouth stopped the bleeding. The child was fed by the rectum. In the afternoon the temperature began to rise rapidly and the child became worse. Stimulants were withheld and morphine gr. 1·200 was given hypodermically. The pulse became more and more feeble and the child died at 6 p.m., the temperature having risen to 103·8°F. At the autopsy the body was somewhat wasted. The organs were normal. A section of the pylorus measured half-an-inch across, the increased thickness to the naked eye appearing to be almost entirely muscular fibres. There was also considerable hypertrophy of the muscular wall of the stomach over the pyloric third.

The pathological specimens were handed to Dr. P. L. Hipsley for further observations and he reported as follows. In Case I. there was nothing unusual about the shape or size of the stomach. The capacity in moderate distension was found to be 4 ozs. (*vide* Fig. 1). The wall was thicker than normal throughout, but the thickening was most marked in the pyloric fourth. The pylorus itself formed a tumour ¾ in. long and about ½ in. thick, being definitely marked off from the duodenum, but tapering away gradually into the stomach wall. On opening the stomach along the anterior wall midway between the greater and lesser curvatures and continuing the opening through the pylorus, the wall of the latter was seen to be about ¼ in. thick, and at its junction with the stomach wall it tapered down to about ⅛ in. A No. 4 catheter could be passed through the sphincter. The portion of the sphincter projecting into the duodenum looked remarkably like the cervix uteri.

Microscopical examination.—On microscopical examination the principal feature to be seen was the hypertrophy of both the circular and longitudinal layers of muscular fibres. The former was five or six times its normal thickness, and the latter was also hypertrophied, but not to the same degree, being perhaps two or three times its usual thickness. The distinction between longitudinal and circular layers was not so sharply defined as in the normal condition. Here and there towards the inner portion of the longitudinal layer bundles of circular fibres could be seen, and in places, moreover, bundles of fibres from the longitudinal layer penetrated the circular and traversed it in different directions and for variable distances. The muscular bundles of both layers appeared to be very densely packed and there was an increase in the amount of fibrous tissue which is usually seen traversing the circular layer. These fibrous bands are very well demonstrated by staining with the Van Gieson mixture, which stains fibrous tissue pink and muscular tissue a yellowish colour. The mucous membrane appeared to be natural, but the submucous layer was thicker than normal and the muscularis mucosæ was distinctly hypertrophied. Very little round cell infiltration could be seen in either submucous or muscular coats. There were no vascular changes to be seen.

The stomach of Case II. presented features very similar to those described in the first case. There was no marked dilatation, if any at all, although unfortunately the actual capacity of the organ was not estimated. The stomach wall was very much thickened in the pyloric fourth, much more so than in the first case. The pylorus formed a tumour about the size of the last joint of the ring finger. (*vide* Fig. 2). A microscopical examination of both the thickened stomach wall and pylorus was made. The latter presented features identical with those described above. In the stomach wall three layers of muscle could be seen. The inner circular layer was about equal to the thickness of the other two combined. All three layers were hypertrophied. The mucous membrane presented nothing noteworthy, but the submucosa was undoubtedly thicker than normal.

CASE III.—Alice B——, was admitted into the North-Eastern Hospital for Children on January 1st, 1906. Her age was 4 weeks, and she was thin but not markedly wasted. She was born fat, and appeared healthy, but ever since the first two days after birth she had been "sick after each feed." She was breast-fed. A week prior to her admission she "vomited immediately after nursing." Her bowels had been confined, and when opened the motions were like "green water," and for three days before she was brought to hospital she had had no action. Another child died of wasting at three months old, fourteen years before. On admission she weighed 5¼ lbs., the pulse rate was 96 to the minute, the respiration rate 32 and the temperature 97° F. Soon afterwards she vomited a large quantity of undigested milk, much more than the previous feed would account for, and the bowels acted freely. A lump was found in the abdomen, about the size of the terminal phalanx of the little finger, hard but not of stony hardness, and with a ridge round it acorn-like. It lay above and to the right of the umbilicus, deep down in the abdominal cavity, very deep, right on the spine, and could be grasped with difficulty between the finger and thumb. When grasped it was obvious enough but it would have been quite easy to miss it, and it required the exercise of great care and patient manipulation for its detection. The stomach walls also felt thick. The child was first examined without an anæsthetic, but subsequently chloroform was administered without, however, facilitating the examination. There was visible peristalsis of the stomach, and this could also be produced by flicking the abdominal walls. Apart from the condition of the pylorus nothing abnormal was found. She was ordered a whey and cream mixture and the stomach to be washed out twice daily. On January 2nd she was sick three times, and the bowels were opened once. She was taking a mixture of tincture of opium, a third of a minim thrice daily for a dose. On the 3rd she vomited eight times and the bowels were not opened. She had lost half a pound in weight since admission. On the 4th she vomited twice directly after being fed. The bowels were opened three times. She had gained ¼ lb. in weight. Olive oil was given in place of the cream, sufficient to make a mixture containing 3 per cent. fat. On the 5th she lost 1 oz., on the 6th, 2 ozs., and on the 7th the weight remained stationary at 5¼ lbs. The olive oil in the milk mixture was thought not to be a success on account of the sickness which had increased to nine times on the 5th, with one exception immediately after feeding, and as on the 6th the vomiting had not improved much it was omitted and cream substituted. On the 7th she vomited eight times, mostly after feeding, and twice the vomit was a "brown fluid." During this period stomach washings were continued, and saline injections were given by the bowel. Albumen water was substituted on this date for the whey mixture. The bowels acted twice daily on the 5th, 6th, and 7th. She retained the albumen water much better than the whey and cream, and only vomited once or twice and in small quantities. Although there had been no further loss of weight, the infant's appearance was not satisfactory, and it was weaker than on its admission. Dr. Carpenter therefore decided to have the child operated upon, the operation being performed by Mr. Ewen Stabb. Ether was administered by the open method, with the occasional addition of a few drops of chloroform. The pylorus was found to be very much thickened, hard and about the size of an almond nut. It was decided to perform a posterior gastro jejunostomy, the pylorus being thought to be too thick and hard for pyloroplasty. The stomach walls were considered to be thickened at the time of operation. Two ounces of whey were injected into the small intestine, which was contracted and looked empty; the stomach, on the contrary, required the withdrawal of some of its contents to facilitate manipulations. The abdominal cavity was well flushed out with normal saline, a quantity being left in the abdomen. The child vomited several

times and the pulse became very weak; on getting her back to her cot it was scarcely perceptible and a mixture of normal saline, adrenalin, and brandy were injected slowly per rectum.

This was not retained, so 8 ozs. of normal saline were injected into the subcutaneous tissue. This had a good effect on the pulse, which became stronger and able to be counted. But she continued to vomit frequently a dark brown material. After one of these attacks the pulse suddenly became worse and could be felt only occasionally; she did not rally and died five or six hours after the operation. *Post mortem*. The stomach was not dilated. Water poured into the

FIG. 4.

stomach through the œsophagus first distended the viscus which held 1¼ ozs., and then passed out slowly through the pylorus. When the funnel was raised to the height of two feet the fluid escaped by drops only. While the passage of fluid was slow the obstruction did not appear very great—five small knitting needles were passed through the pylorus easily, as also a No. 2 catheter, and the diameter of its lumen was 2 inches. The indurated pylorus measured ¾ in. by ½ in., and the stomach walls were thickened. The operation sutures held well and there was no leakage. There were no other abnormalities.

Remarks.—These cases, in respect to the cartilaginous hardness of the pyloric tumour and to the hypertrophy of the stomach walls, resembled a case recorded by myself and Mr. Lockhart Mummery in Vol. 5 of Reports of the Society for the Study of Disease in Children, pp. 242-245, two drawings being given, one of which I reproduce—*viz*., Fig. 5.—This patient, æt. 3 months, was operated upon by pyloroplasty, but died the following morning. The *post mortem* showed that a free opening had been established through the pylorus, and, mechanically, the operation was a success. It is not always easy to feel a hypertrophied pylorus, for the tumour is often deep down in the abdominal cavity and is apt to be missed on palpation, but by methodically squeezing the abdominal contents between the fingers and thumb the condition of the underlying viscera can be readily ascertained. This method of examining infantile abdomens, which is a very delicate one and yields admirable results, should always be practised as a matter of routine. In Case III. the thickened pylorus was especially difficult to feel, and the squeezing method of abdominal examination proved invaluable Loreta's operation was not attended by success in Case I. The infant recovered from the shock of the operation but the stenosis recurred and starvation from mechanical causes followed.

Case II. did not survive the shock of operation which took the same time to perform—viz., 25 minutes, as the case of pyloroplasty previously mentioned. The condition of the pylorus was much the same as in that case, and if pyloroplasty had been attempted the same result would have doubtless followed.

The operation in Case III. was as expeditiously performed as in Case I., but like it, death occurred from shock shortly afterwards. The physical condition of the infants could not be considered good in any of the cases, but regarding them in the light of examples of marasmus they had by no means reached that condition of body which is usually recognised as past hope of recovery. In the diagnosis of congenital hypertrophic stenosis of the pylorus too much importance must not be attached to the absence of characteristic vomiting—the retention of two or three feeds followed by their subsequent expulsion. Peristalsis of the stomach is not unknown in simple gastric disorders in infancy, quite apart from stenosis of the pylorus, and unsupported by other signs must not be taken to indicate the latter.

Perhaps the most important diagnostic sign is the detection of the pyloric tumour, but even this may prove a source of error, for an enlarged abdominal gland has been mistaken for this condition in an infantile dyspeptic and has been revealed surgically. While in my cases the medical treatment has not been successful, surgical measures have proved no less unsatisfactory. Unfortunately, the extent of the pyloric stenosis was such as to render the performance of a secure and permanent operation in quicker time an impossibility. On the one hand the infants were faced by slow starvation, and on the other by death from shock. But is there no middle course for these pronounced cases? Failing relief by a well-adjusted dietary free from coagulum, would it not be better to perform a preliminary jejunostomy, which could be done very quickly? Feed the child by the artificial opening until such times as it is better prepared to resist the shock, and then proceed to the major operation? I think so, and the next case that comes under

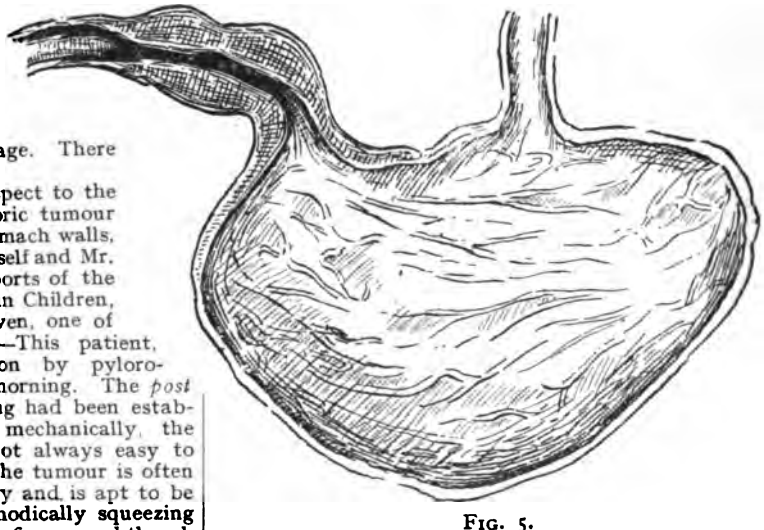

FIG. 5.

my care I shall adopt this plan. My thanks are due to Dr. E. Douglas Wolff for the photographs of Cases I. and II., and also for the careful records kept by him.

PLANTAR REFLEXES.

By W. B. WARRINGTON, M.D.LOND., F.R.C.P.,
Physician to the David Lewis Northern Hospital, Liverpool.

THE recognition in clinical medicine of the importance of the doctrine of reflex action is chiefly due to Marshall Hall, but the study of cutaneous reflexes at a later time became somewhat neglected, partly because the discovery by Erb and Westphal of the significance of the tendon reflexes, of which the knee-joint is the prominent example, led to such immediate advances in the study of nervous diseases. No such importance could then be claimed for the cutaneous reflexes, but in 1896 their study, and especially the study of the plantar reflex, received a remarkable impetus by the announcement of Babinski, a Paris physician, that there was an essential difference between the form of response to plantar stimulation in healthy or hysterical persons, and in those suffering from organic disease of the pyramidal tract, and that hence a boundary could be fixed between two domains, each of very wide extent. Numerous observations were made in all parts of the world, and papers on the plantar reflex still continue to appear. This fact, which also indicates that a settled value has not yet been assigned to the phenomena, is my apology for addressing you. Limit of time forbids my entering into the physiological side of the subject, and I shall confine my remarks to stating as briefly as possible the result of my own personal observations.

Method of observing the Reflex.—This is important. In all cases the patient should be lying down, with the knee bent and the muscles kept relaxed. The sole of the foot should be dry and warm, and its dorsum firmly grasped by one hand of the observer. If the patient is intelligent, he may often usefully be told that the sole of his foot is about to be tickled, and asked to concentrate his attention elsewhere. The instrument used for stimulation does not matter much—the finger, a wooden match, the point or head of a pin answer equally well. The stimulation is best made from the heel to the point of the foot. In the vast majority of healthy persons at least after several attempts, separated by an interval of time, a quick movement of the lower limb results, the tensor fasciæ femoris probably first contracts, and then, in rapid succession, the toes are flexed and adducted, the ankle dorsi-flexed and inverted, and the knee and the thigh flexed. This movement, when involuntary, is the normal plantar reflex, or flexor response. Not all the movements mentioned may take place; this depends on the strength of the stimulus, the irritability of the skin, the emotional state and capacity for attention of the person.

The movement of the toes is the important one. When thus taken, the reflex is rarely absent, but may be so, and this absence may be unilateral.

The reflex is absent in disease wherever the reflex arc of the first sacral nerve is interrupted, and also in complete transverse lesions of the cord. It is always absent in hysterical anæsthesia, and may be absent in that morbid condition even if anæsthesia is not present.

Quite different is the reflex described by Babinski. Here there is a deliberate slow extension of the great toe, usually associated with spreading or extension of the other toes, the further movements of the limb being much the same as in the normal flexor response.

I shall allude hereafter to this as the characteristic or typical extensor response, and I beg leave to ask your attention particularly to the slow and deliberate nature of the movement, since other varieties of extension are met with. These may have also a high value, but the same certainly does not belong to them. They will be mentioned as I proceed. One of the difficulties surrounding the clinical observation of the plantar reflexes is, that they may be closely stimulated by voluntary movement. The difference is better realised than described, but the following points may help. The true reflex is more mechanical in appearance; it commences and ceases suddenly, and the limb in a moment assumes its original position; a voluntary movement, on the other hand, sets in later, has not the same mechanical appearance, seems to be under some control, and the limb does not at once reassume its original position. I proceed to give an account of my observations in different diseases.

Disseminated sclerosis.—On account of the frequency with which young women are attacked by this disease, and the fugitive or anomalous nature of the opening symptoms, the extensor toe reflex was welcomed as a valuable sign for the distinction between this grave organic affection of the nervous system and hysteria. If present in the characteristic form, even in the absence of other symptoms, I should greatly hesitate to diagnose a purely functional condition; yet, in the cases I have so far met with, other symptoms, sufficient to put the observer on guard, have been present; 7 presented the classical picture of disseminated sclerosis; of these, 3 gave the characteristic response; in 1, combined with permanent hyper-extension of the great toe, an appearance always strongly suggestive of pyramidal disease; 1 gave a more rapid extensor response, in 2 alternation of extensor and flexor was present, and in 1 no reflex was obtained. The 5 remaining cases were probably atypical forms of the disease, and all gave the full, slow extensor response. In 1 the K.J. and A.J. were absent; here the presence of nystagmus, combined with extensor response, eliminated tabes; whilst this symptom, with the presence of partial optic atrophy, eliminated subacute combined sclerosis, leaving only the diagnosis of disseminated sclerosis. It is, indeed, in the differentiation of the different forms of organic disease that I personally have obtained most value from the sign.

Apoplexy.—The extensor response appears at once after the seizure, and was present in 9 out of 13 cases on the paralysed side. In 3 the plantar reflex was absent, and in 1 flexor in type. In apoplexy the response is usually more rapid and of shorter duration than the characteristic movement. It was in one of these cases that I obtained the extensor reflex in the toes by stroking the leg and thigh downwards. To a reflex thus elicited the names of planti-tibial and planti-crural have been given, and I think it is of considerable importance, but further investigation is much needed. On the non-paralysed side I found the flexor response in 10 cases, in 2 an extensor response, and in 1 the reflex was absent. It seems that the sign may give evidence as to whether a destructive lesion has invaded both sides of the brain, though it must be remembered that as the pyramidal tract on one side is in part in connection with both hemispheres, a double extensor response may be present in a hemiplegia, as in 2 of my cases, yet in 8 it was unilateral. It may also aid in distinguishing apoplexy from poisoning, though here much evidence is wanting, which can best be supplied by resident officers, to whom I respectfully commend this study. I am unable to attach any prognostic value to the presence or absence of the sign.

Meningitis.—The stimulation of meningitis in many fevers by the group of symptoms called "meningismus" suggested that the sign might be of value. It certainly appears to be often present in the former, absent in latter. Lumbar puncture is, however, a much more certain way of distinguishing between the conditions. My own observations are few. A rather rapid extension in two cases of tuberculosis, a flexor response in two of pneumococcal meningitis.

Transverse incomplete lesions of the cord.—In these cases the most characteristic response is met with. It was present in each of 12 instances, 5 being pressure from caries, 7 inflammation or softening of the spinal marrow. If the pressure is relieved or the primary disease subsides, the flexor response may return.

Complete transverse lesions of the cord.—The extensor response is here the only reflex that remains. It is, however, often absent, as in my 3 traumatic cases. In primary disease which has destroyed the whole transection of the cord its presence is often an important diagnostic sign, giving a clue to the original condition.

Gross cerebral disease of one hemisphere, other than

the result of old apoplexy. The nature of the reflex depends on the position of the lesion in the brain. It may be very serviceable, as in the following instance. A patient known from other symptoms to have a cerebellar tumour. Where was it situated? On the right side the knee and ankle jerks were absent, but there were very brisk cutaneous reflexes—abdominal, epigastric, and cremasteric—with the normal flexor response—a combination much opposed to that which is found when the pyramidal tract is interrupted. On the left side the reverse was found—brisk deep reflexes and extensor toe response, with the absence of cutaneous reflexes. The diagnosis was therefore made that the growth was on the right side, pressing on to the pyramidal tract before it had crossed. The correctness of the inference was demonstrated at an operation, and, unfortunately, later at the autopsy.

Post-epileptic coma.—The exhaustion produced in the cerebral cortex may suspend the functional activity of the pyramidal tract, and an extensor response result. It was so in 4 cases I observed. Its presence may serve to distinguish epilepsy from hysteria.

It was also present in one case of post-epileptic hemiplegia of long duration.

Cerebral diplegia.—Extensor response usually present, even when ankle clonus cannot be obtained; but it must be remembered that this form of response is normal to children before they can walk.

Tabes dorsalis.—Unless the pyramidal tracts are involved, the extensor response never occurs. The flexor response is the rule, but this is absent if there is much anæsthesia in the region of distribution of the sacral roots.

Peripheral neuritis.—Never an extensor reflex. The response is either flexor or absent if anæsthesia is present. Lastly, 2 cases may be cited illustrating its value in differential diagnosis:—

1. A patient under the care of Mr. Murray. Fracture of last lumbar vertebra. Had the cord or the cauda equina been damaged? The knee-jerk was absent on both sides, but ankle-jerk present, and characteristic extensor reflex. The inference was, therefore, that the lesion was in the cord at the third lumbar segment.

2. The reverse of this. Patient under Mr. Harrison's care. A man had been injured in the lumbar region. He was found to have an absent knee-jerk, but ankle-jerk present, with flexor response. It was inferred that the third lumbar root had alone been injured.

CONCLUSIONS.

1. The full, slow, deliberate extensor response is highly characteristic of organic interruption by the influences traversing the pyramidal tract, and has a value nearly approaching that of true ankle clonus. It does not occur in healthy adults when awake. It is constant in its appearance and easily produced, and cannot be well simulated by voluntary movement.

2. An extensor response, shorter in duration, of smaller range and more immediate in appearance, is usually found when the lesion of the pyramidal tracts is more physiological than anatomical, as in the exhaustion of the cortical cells after epilepsy, or the pressure of exudations, as in meningitis. It may be met with in slighter anatomical lesions, and is sometimes replaced by a flexor response. In such cases especial care must be taken to eliminate voluntary movement.

3. An alteration of flexion and extension may be obtained. In these cases, if the flexion and extension are of equal range and rapidity, great caution must be observed in the interpretation. The movement may be voluntary, or it may indicate a condition of pyramidal equilibrium due to slight damage, as described by Stanley Barnes. If the flexion, however, is very small in range, while extension is slower and larger in range, its significance must be carefully considered.

4. The reflex is absent in anæsthesia of the sole from any cause, excepting that resulting from complete transection of the cord.

5. The absence, when other considerations indicate a lesion of the pyramidal tract, is of no significance.

CLINICAL RECORDS.

THE WESTMORLAND LOCK (GOVERNMENT) HOSPITAL.

The Delivery of Women Suffering from Venereal Sores.

BY SEYMOUR STRITCH, L.R.C.P., L.R.C.S.,

Late Resident Medical Officer to the Hospital.

AT the meeting of the Obstetrical Section of the Royal Academy of Medicine, held on May 25th, the Master of the Rotunda Hospital read his annual report, and in it alluded to the delivery of women suffering from local venereal sores. In the discussion that followed, other gentlemen referred to the same subject, and described the prophylactic measures they considered necessary to prevent toxæmic infection arising during the puerperum. Dr. Jellett suggested that such sores should be curetted, and then treated with formalin.

As a former resident medical officer of the Westmorland Lock (Government) Hospital, I had the honour of announcing the results obtained in the treatment of such cases in that institution.

In his reply, Dr. Hastings Tweedy was good enough to say that such results as I had described were very interesting, and in his opinion they should be published. Encouraged by this statement, I now beg to submit the following particulars relating to the delivery of women in the Lock Hospital.

Through the courtesy of Dr. Henry FitzGibbon, Senior Visiting Surgeon to the Lock Hospital, I have been furnished with a table of statistics showing that there have been in this hospital 199 confinements in the course of the last ten years. These figures include cases of abortion, miscarriage, and full-term births, the greatest proportion consisting of the last-named. Amongst all these deliveries there were no maternal deaths. Only one patient developed serious symptoms with a high temperature as a result of septic absorption. Dr. FitzGibbon further states that no fatality occurred in the fifteen years preceding the ten just alluded to. That is to say, for a period of twenty-five years no lying-in women died in the Lock Hospital. Taking an average of twenty confinements per annum for twenty-five years gives us a total of 500 cases. In reality these figures should be greater, owing to the fact of the number of admissions to the hospital having decreased about 45 per cent. in the last fifteen years. If figures prove anything, or may be taken as a criterion as to the efficiency of any system in the treatment of patients, I think it must be conceded that women confined in the Lock Hospital are adequately attended to. The fact that only one case of septic fever occurred amongst 199 labours should be sufficient justification of the antiseptic precautions carried out in this institution.

Dr. T. P. Beddoes, Registrar of the London Lock Hospital, has very kindly sent me a letter in which he states: "This hospital is a private institution, and does not admit pregnant women, and if by accident they are admitted, as soon as their condition is ascertained they are discharged." Yet they have a certain proportion of abortions and confinements. Amongst these only one woman died, the cause of her death being placenta prævia, which accident can in no way affect our figures. Dr. Beddoes made his search through the records of his hospital to extend over a period of twenty-five years, with the result stated.

It will be noticed that the statistics of these two institutions, each covering a like period of twenty-five years, do not record a solitary instance of a puerperal patient succumbing from venereal causes. This exemption from general septic infection amongst patients suffering from venereal disease cannot be explained on the supposition that they may have been for some time in hospital and under treatment, for, as in ordinary lying-in hospitals, it frequently happened that these women were admitted towards the end of the second stage of labour.

Though speculative theories are beyond the province

of this communication, I might be permitted to say that the natural flushing of the genital tract by the liq. ammonii is at least not the essential factor of this exemption from general infection. This was illustrated by a case admitted to hospital in whom the "waters" had accidentally burst and dribbled away before the "os uteri" showed any signs of dilating. This patient had a lingering labour of about thirty-six hours' duration, yet her convalescence ran a normal course. It was supposed that driving in a cab from the Rotunda Hospital, where she stated she had been refused admission, had caused the membranes to rupture.

Until March, 1903, t ere were no special facilities for the delivery of women in the Dublin Lock Hospital, certainly there were none till the close of my residency, when a labour ward was opened. Previous to this, the confinements were conducted in a common ward, the patient being merely moved from one bed to another on the completion of her labour.

Nor were these patients in any way isolated from the others, whom I think may all be described as being "septic" in the Rotunda interpretation of the word. They enjoyed no such privileges as private bed-pans. In fact, beyond the temporary disturbance and excitement entailed by their actual confinements, things continued in much the same way as before. They, however, now became the patients of the resident medical officer, and had their diet changed to suit their altered condition.

The preparation of a woman entering on labour was supervised by the maternity nurse, who was, I believe, one of the most thorough, reliable, and efficient midwives who ever obtained a diploma in the Rotunda Hospital. This nurse, Nurse Halpenny, had over twelve years' experience in nursing Lock Maternity cases. I, for one, of the "residents" whom she passed through her hands, deem myself fortunate in having been initiated by her into the best means of avoiding accidental inoculation of oneself, whilst at the same time learning how to successfully prevent septicæmia in the patient. Nurse Halpenny's experience being so extensive, I never interfered in the conduct of a confinement unless some special indication for instrumental or manual assistance became apparent. According as a patient had no discharge or local sores, or had a simple catarrhal discharge, or suffered from a purulent blenorrhagia and a septic condition of the parts, Nurse Halpenny varied her procedure.

In the first instance, she satisfied herself with a most thorough cleansing of the patient's pudendum, perineum, and thighs. In the second instance she added douching of the vagina with a solution of perchloride of mercury. Whilst, in the third and most important class of cases, she substituted for the douching a gentle prolonged syphon irrigation of the vagina, lasting not less than twenty minutes. After this and during the continuance of labour, the parts were repeatedly flushed by turning on the syphon. These means were supplemented by using a generous supply of "wipes" made of absorbent wool or butter muslin the antiseptic use for disinfection being a weak solution of creolin or lysol.

The patient was touched by the hands of her attendants as little as possible. Post-partum douching was never practised, except in cases where the uterus had been entered either by instruments or the hand.

Personally, I used gloves whenever interference became necessary, though I do not think that this was the custom of my predecessors. In the Lock Hospital one learnt to avoid all possible risk of cutting one's hands, and any abrasions were carefully sought for and painted with flexile collodion.

Immediately on the completion of the third stage of labour a drachm of the liquid extract of ergot was given to the patient, followed by a similar dose in thirty minutes, after which, on every third hour for three occasions, half a drachm of this preparation was administered. In addition to this I invariably prescribed a bottle of quinine, which lasted till the sixth day. Usually, on the tenth day the woman was transferred back to the care of her visiting surgeon and resumed her former specific treatment.

Concerning the infants, the main anxiety in their case was to prevent their eyes becoming infected. For this purpose the nurse stood ready with "wipes" for their ablution, and the moment they appeared at the vulva they were washed till clean. Silver nitrate solution was not used, and whilst I was in the hospital no case of ophthalmia neonatorum occurred, though subsequently to their birth some children developed a more or less severe conjunctivitis from which they made good recoveries. These may be considered, perhaps, as accidental occurrences, caused by any one of the numerous and obvious dangers infants are exposed to in such a hospital. No sooner was a baby born than every woman in the ward and building seemed moved by a common desire to nurse it, and in spite of the vigilance of the staff they no doubt sometimes succeeded in doing so. The most frequent sequelæ of gonorrhœa in a pregnant woman in my experience was suppurative mastitis, sometimes of enormous extent.

Pyosalpinx is stated by German gynæcologists to be caused by gonorrhœa in a proportion of one-fifth of all cases of this condition. Of 2,078 cases, 279 were diagnosed on clinical data to be in consequence of gonorrhœa, and where accurate bacteriological investigation was undertaken, Wertheim found that 76 cases, out of a number of 376 of pyosalpinx, were due to gonococci bacilli (Hart and Barbour, "Encyclopædia Medica," vol. iv.). Yet it is a remarkable fact that practically no case of pyosalpinx appears amongst the records of the Lock Hospital returns. It was the opinion of the visiting surgeons (1903) that pyosalpinx was rather an accidental sequence of gonorrhœa, due to injudicious douching, the use of the uterine sound, or to labour occurring after a recent gonorrhœa.

Dr. F. J. M'Cann, physician, Samaritan Free Hospital, London, in his contribution on gonorrhœal infection in the "Encyclopædia Medica," appears to me to share somewhat similar views.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Case of Villous Papilloma of the Bladder with Symptoms Referred to the Hip-Joint.

By JOSEPH CUNNING, M.B., F.R.C.S.

A MAN, æt. 52, came to the out-patient room with pain which he referred to the hip-joint. He had already been seen a week before, when he was found to have ankylosis of the left hip-joint, some shortening and also considerable enlargement and prominence of the great trochanter. He said the trouble in the hip had been going on for about a year. The symptoms had all been attributed to the hip-joint. He now brought up with him a sample of his water, which it was easy to see was composed of nearly pure blood. Inquiries showed that the bleeding had been going on at intervals for nearly two years, and the pain which he had referred to the hip was always exaggerated at the time of the bleeding, and then was of the character of renal colic. He had been quite free from bleeding at intervals of from one to two months. There had been no frequency of micturition, and there was no enlargement or tenderness of the kidney. A diagnosis of villous papilloma of the bladder was made because, as Mr. Cunning pointed out: (1) Cases of intermittent profuse hæmaturia were most commonly due to growths in the bladder; profuse hæmorrhage from the kidney was very much less common; (2) the growth was almost certainly a villous papilloma, because of its slow progress; and (3) the fact that the patient returns to the normal state and the hæmaturia entirely ceases for one to two months was an important point of distinction between villous papilloma and a malignant growth; the symptoms of bleeding

and pain in the latter never entirely disappear; (4) no infiltration could be felt at the base of the bladder *per rectum* or bimanually; (5) the growth was probably situated at the left ureteric orifice, for villous growths rarely produce pain apart from cystitis, unless at one of the orifices; if at the ureteric orifice they produce symptoms resembling those of stone in the bladder. The only way to satisfactorily clear up a case of this kind, Mr. Cunning said, was to examine with the cystoscope. As the bleeding had practically ceased at the time a cystoscopic examination was carried out. The urethra having been cocainised, the bladder was washed out till the fluid came back perfectly clear. On examination with the cystoscope the papilloma could be distinctly seen looking like a mass of pink waving seaweed, and, as suspected, growing from the neighbourhood of the left ureteric orifice. There were no secondary masses of growth in other parts of the bladder. A suprapubic operation was recommended, and stress was laid on the importance of removing a portion of the submucous tissue with the papilloma in order to avoid the possibility of recurrence. Mr. Cunning pointed out that it was lucky that this patient had brought his urine on his second visit, as when first seen he had given no urinary symptoms but only complained of the hip, which was undoubtedly diseased but the disease there had then really worked its own cure. With regard to the prognosis, Mr. Cunning thought that in men over 40 although these cases microscopically presented the appearance of innocent growths, yet there was a very marked tendency to recurrence in other parts of the bladder, so that operation was very much less satisfactory than in younger people. With multiple papillomata the patient was bound to get cystitis and extension to the kidneys, so that he ends in suppurative pyelo-nephritis. The removal of a part of the submucous tissue he had before alluded to gave, he considered, in young patients a good chance of non-recurrence, but in an older man, even with this precaution, the chances of non-recurrence would be far less. In cases which could not be operated on because of the extensive character of the growths, the best plan to adopt, he thought, was to cocainise the bladder, and then inject a 1 per cent. solution of resorcin; this had the effect of shrivelling the papillomatous tendrils which the patient subsequently passes in his urine.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

DUCT CANCER OF THE BREAST IN A MALE.—Mr. H. BETHAM ROBINSON operated on a stout man, æt. 64, who had been admitted on June 11th, 1906, with a tumour in the left breast. The patient gave the following history: Nothing abnormal had been noticed until last Christmas, when on stooping down some inconvenience was experienced owing to the lump in the breast. At this time the lump itself was said to have been the size of an orange; there had been no pain before or since, and he had complained of no special inconvenience except from the main feature of the disease, namely, exudation from the nipple. The man said he had lost flesh during these last six months, and had felt languid and worried. On admission both breasts were extremely well developed, but this was only in relation with the general superfluity of fat. The left breast was unduly prominent in the nipple region, and on examination there was to be felt a well-marked lump occupying the upper and outer quadrant of the gland; this lump was not larger than an orange, and over it the skin was free and the mass itself quite movable on the deep structures. It was definitely cystic, and on pressure a dirty brown fluid came from the nipple at its upper part; the nipple itself appeared a little drawn in at the upper part. There was some indefinite fulness in the left axilla, but it was impossible to distinguish individual glands owing to the large amount of fat. His general condition of health beyond this was quite satisfactory. The diagnosis of the case was a cystic tumour arising from the larger ducts in the nipple region, because of the characteristic discharge and the relationship of the growth to the breast structures. Whether this growth was innocent or malignant it was, Mr. Robinson said, impossible to decide before operation, but he felt convinced that it would prove malignant because of its size, the indefinite fulness in the axilla, which probably indicated secondary glands and the evident loss of flesh. On June 13th, the breast was freely removed and the axilla entirely cleared of its fat. This was shown to be essential by the presence of several discreet glands scattered through the mass of fat. Section of the tumour showed several cysts, each about the size of a walnut, and in nearly all of them were intra-cystic growths of a firm bossy character. There was also evidence that the growth involved the wall of the cysts and surrounding connective tissue. The axillary glands on section gave evidence of probable secondary deposits. The diagnosis expressed as to the probable malignancy of the growth was supported and has been confirmed since, on histological examination, the nature of the tumour being duct cancer, composed of calumnar and cubical epithelium. Mr. Robinson said that of course tumours in the male breast were not frequently met with, but this particular form of growth in a man was especially rare. This discharge from the nipple was, he pointed out, the most characteristic feature of swellings arising in the ducts, but when the growth was purely local it was almost impossible to say before histological examination whether it was simple or malignant. In his experience the most innocent-looking papillary tumour in the majority of cases gave histological evidence of malignancy, so much so that he would be inclined to regard all of them as malignant, and accordingly would advise a very guarded prognosis to be given in such cases. Fortunately, he said, the standard of malignancy in this form of growth was decidedly lower than in common spheroidal-celled breast tumours, so that free removal offered a more hopeful future to the sufferer. Although such growths in the ducts of a man's breast were rare, yet he thought that, on the supposition that the ducts in the male breasts would be more developed than the glandular tissue proper, these growths, in a search perhaps through all the reported cases, might be shown to be proportionately greater than was at present considered. The wound healed by first intention.

ITALIAN HOSPITAL IN LONDON.

A CASE OF SARCOMA OF THE TONGUE.—Mr. LENTHAL CHEATLE operated on a woman, æt. 52, who presented a round, defined solid swelling in the right side of the tongue at about the junction of the anterior two thirds with the posterior third under the mucous membrane. No lymphatic glands were enlarged, and the surface of the tongue was normal. The growth had been noticed six weeks ago. An encapsuled tumour was easily removed from the submucous and inter-muscular tissue, without hæmorrhage, by means of a longitudinal incision over the swelling of about one and half-inches in length. The wound was sewn up with catgut.

Mr. Cheatle pointed out that the mouth had been prepared beforehand with a view of preventing sepsis. Her teeth had been well scrubbed and old teeth stumps

removed. The tumour on being incised appeared of uniform consistence and was, Mr. Cheatle said, either a fibroma or a sarcoma. A section was made. There was no glandular tissue. It was composed of spindle cells with large nuclei; the blood vessels were not highly organised, and although there was a history of rapid growth, the structure of the tumour suggested a not very malignant form of sarcoma; but he thought it was wise not to lay too great stress upon the microscopical appearances when the degree of malignancy was in question. Although the tumour had been widely removed, the case would, he remarked, be carefully watched in the future. He asserted that sarcoma was a rare disease of the tongue. He did not know exactly the number of examples recorded, but he believed it would not amount to forty well authenticated cases.

SPECIAL REPORTS.

THE PUBLIC HEALTH CONGRESS AT CORK.

THE opening meeting of the Congress of the Royal Institute of Public Health was held in the Queen's College, Cork, on the 27th ult., the City High Sheriff, Mr. R. H. Beamish, presiding.

Professor Smith, having invested President Windle with the President's badge of office, the latter delivered his inaugural address.

Having welcomed the Congress to Cork, he said they had come to a country where matters of public health were, perhaps, as badly in need of public interest and attention as in any country in the world, for no other country presented such great possibilities of happiness and health and no other country presented a similar picture of misfortune and decay. If there was a country in the world which should be healthy, happy, and prosperous, filled with strong men and women, lusty children, and smiling homesteads, it was this land. In respect to health, they were far, very far, from being where they should be. On the contrary, they were the prey of evils which seem to be increasing rather than diminishing as the years rolled by. Year by year the death-rate from consumption had been steadily declining in England and in Scotland, and as steadily increasing in this country. Side by side with this advancing rate of mortality from tubercle, there had been an alarming increase in the number of the insane. Of every 10,000 persons in Ireland, 52·6 were registered as lunatics or idiots. It was, unfortunately, only too true that lunacy was on the increase in England and Wales also, but the actual figure there was 34·71 per 10.000. The emigration curse, which year by year drained away the life-blood of our race in the shape of its youngest, its most promising, its most valuable members, had, in his opinion, a great deal to do with that. It had been said that what was happening here was a survival of the unfittest. He would like to ask the local authorities whether they were doing all that was in their power to stem the tide of disease? Were they taking all the advantages that they could from the Public Health Acts, from the Housing Acts, from the other enactments which have from time to time been passed with the view of improving the health of those whom they had been elected to watch over? Were they making use of the provisions for the notification of disease, and particularly of the tuberculosis disease, from whose ravages we are so severely suffering? Were they helping the medical profession in its struggle against the enemy by appointing bacteriologists in the towns and in the counties? But it was not only public authorities who had a responsibility in this matter. It was one in which the general public was deeply interested, and in which it also had its part to play, if the country was to come safely through this present period of trial. And he would, therefore, like to ask the members of the general public whether they were keeping an eye on their Public Health Committees, with a view of seeing whether those Committees were doing all that they could to preserve the public health? Were they trying to help those associations which were doing their best to bring about a better state of affairs in connection with the health of themselves and of their neighbours? Were they doing anything to promote temperance or a better housing of the poor?

On the motion of Alderman Dale, seconded by Mr. Stanley Harrington, a vote of thanks was passed to Dr. Windle for his address.

Speeches in support of the motion were made by the Mayor of Folkestone, the Mayor of Birkenhead, Sir John D. Littlejohn, M.D.; the High Sheriff of Limerick, Sir Charles Cameron.

On the following day the Congress met in four sections—(1) Preventive Medicine, (2) Child Study and School Hygiene, (3) Engineering and Architecture, (4) Bacteriology and Chemistry.

Among those who took part in the various discussions were Dr. Hope, of Liverpool; Dr. McWattee, of Dublin; Dr. Marsden, of Birkenhead; Dr. Donovan, of Cork; Rev. O. J. Hickey, of Waterford; Mr. Wall, Mayor of Birkenhead; Judge Gibson, of Edinburgh; Dr. Browne, of Cork; Dr. Corby, of Cork; Mr. Wallis-Hore, of Cork; and Mr. J. Kelly, of Dublin.

CENTRAL MIDWIVES BOARD.

MEETING HELD JUNE 28TH, 1906.

The President, Dr. CHAMPNEYS, in the Chair.

AT the beginning of the meeting the Secretary read a letter from the Clerk of the L.C.C., saying that Dr. Wanklyn had reported the Whitechapel Infirmary structurally unfit for a training school for midwives.

Upon the question of examinations being held in Welsh for Welsh midwives, it was agreed that Dr. Walford, M.O.H., for Cardiff, be asked whether in his opinion the difficulty would be met by the presence of an interpreter at the Oral Examination.

A letter from Dr. Gordon, Hon. Sec., Salisbury Division B.M. Association, enclosing copy of a resolution as to the form to be filled in for sending for medical aid, was read and answer was returned that the draft copy of Rules now under consideration by the Privy Council met in part the objections raised.

Mr. WARD COUSINS thought midwives should certainly be instructed that the form did not entail the compulsory attendance of a medical man, and again he would ask who was to pay the fee for such attendance.

The PRESIDENT considered that the midwife made herself responsible for the fee by sending for him.

A letter was then read from Dr. Walford, M.O.H., Cardiff, saying he had good reason for believing that a midwife who received pupils had the certificates signed by Dr. D. E. Powell, of Cardiff, though the latter had not personally supervised all the cases for which he signed.

It was arranged that Dr. Powell be asked for an explanation, but

Mr. WARD COUSINS remarked that he could sign under the rules. He knew general practitioners who gave 20 cases to their midwives and then signed certificates though they themselves had not superintended the cases. Such matters ought to receive most serious attention from the Board.

Since the last meeting a Standing Committee had met to consider what answer should be returned to the Privy Council *re* making Dublin an Examining Centre, and at the present meeting it was recommended that the Privy Council be informed that the Board had carefully considered the memorandum handed to the Lord President during a recent visit to Dublin. The Board suggested that as it is now proposed to defray the expenses of an examination in Dublin by a special contribution, the difficulty might be

met by those interested in the matter paying the travelling expenses of candidates to an English centre That the work of the Board being supported by English rates, etc., they could not use it for Irish expenses.

Mr. WARD COUSINS remarked that the Board had no control over midwives practising in Ireland, and

Dr. PARKER YOUNG added that Ireland had in the beginning wanted to keep out of the Act and now found she had made a mistake. It was to be hoped Dublin did not intend raising the money by raising the examination fee, as that was contrary to the Act. They would never succeed in satisfying Ireland, and he did not think it wise to extend the area of examination centres.

Miss PAGET agreed, adding that if Dublin were satisfied Belfast would not be. It would be quite easy for the women to come to Liverpool.

It was finally agreed to send in the answer to the Privy Council and discuss the matter further when further communications were received.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 1st, 1906.

AT the Hufeland Society, Hr. Ewald showed preparations from a case of

THROMBOSIS OF THE PORTAL VEIN.

The man. æt. 36, from whom the preparation was taken, went to the Augusta Hospital on April 23rd. Before this he had been a healthy man; whilst a soldier he was said to have had gonorrhœa. For two years he had suffered from pain in the stomach and headaches. Up to April 19th, he had performed his duties as keeper in a prison. Since then he had complained of frequent spasms in the lower part of the abdomen, and on both sides shooting towards the chest. Three or four times a day he had attacks of vomiting of greenish material. These lasted about twenty minutes each time. The cramps came on suddenly and were frequently accompanied by hiccough; the bowels were obstinately confined, but they acted under enemata. He was a powerfully built man, but much reduced. There was no jaundice, very slight glandular swellings, the liver somewhat disturbed, the spleen enormously enlarged and of hard consistence. The stomach contained about 80 ccm. of bile like material, no free hydrochloric acid, but abundant chlorides, and no blood. There was no fever, slight dulness in the lower part of the abdomen. No symptoms of stenosis were present; strong indican reaction in the urine. The general condition and pulse very good. Rectoscopic examination showed a good deal of swelling and softening of the mucous membrane, and some punctiform hæmorrhages. On the third day there were violent pains, and a good deal of hæmorrhagic vomit. Fæces hippocratica. The pulse went up to 156. Ice water washings out and infusion of saline solution. The patient died during the night. The speaker suspected thrombosis of the mesenteric artery, or of the mesenteric veins. Against this view was the absence of ascites, of jaundice, and of blood per rectum. The whole case was opposed to ulcer of the stomach. The autopsy revealed thrombosis of the portal vein. Both stomach and intestines contained a large quantity of blood. That syphilis was a cause of pylophlebitis was an acquisition of recent date. Usually excessive changes in the liver preceded thrombosis of the portal vein.

He also related the case of an elderly woman who died with symptoms of carcinoma of intestine. The autopsy, however, only showed chronic dysentery, and no trace of malignant disease. Cases of chronic dysentery in old people without any demonstrable etiology were not so rare.

Hr. Grawitz confirmed the statement that chronic inflammations of the bowels in old people were frequent and difficult to diagnose during life. They could be more correctly described as chronic colitis originally di htheritic, later necrotic. He always had the impression that the condition was caused by mercury.

Hr. Ewald then described a case of

LEUCÆMIA WITHOUT LEUCÆMIC BLOOD.

The powerful but much emaciated man was in the hospital six days. There was no sternal pain. There was a systolic murmur over the heart. There were no glandular swellings, and the spleen was not tender. The liver was slightly enlarged, but not particularly tender. The motions contained no blood, but there was hæmorrhage into the retina. There were no tubercle bacilli. Death took place after a rigor and rise of temperature. Examinations of the blood were made almost daily, but without discovering anything special. The spleen was considerably enlarged. There were circumscribed hæmorrhages in the stomach. The speaker went through the various diseases that might come into question in the case, and decided for the clinical diagnosis "leucæmia," as the blood might undergo changes under the influence of intercurrent diseases.

At the meeting of the Verein f. Schulgesundheitspflege, Hr. Neufert spoke on so-called

FOREST SCHOOLS (WALDSCHULEN).

In a lengthy address, the substance of which is as follows, he said that children suffering from chronic ailments, unfitted for regular attendance at school, should be separated as much as possible from the other children in schools in which their faulty bodily and mental developments would be taken into consideration. A school in the woods with shortened hours of instruction, with sufficient provision for recreation, as in the Charlottenburg Waldschule, was suitable. The hygienic aim of wood-schools was the strengthening and recovery of chronically unhealthy children by simple hygienic and medicinal means—residence in the forest and copious sunlight, strengthening diet, and suitable bathing. The pedagogic aim was to bring the children forward with their education as quickly as their bodily and mental condition allowed, so that on their return to their ordinary schools they would be able to keep pace with their companions in the classes as before. In the class grouping in the forest schools only teaching and hygienic points were to be considered; the sexes, therefore, need not be separated and no dogma should be taught. It was desirable to prolong the period of the forest schools over the milder winter months. For a proportion of the children needing the forest school, a sanatorium attached to it was desirable, in which children could be cared for night as well as day.

Prof. Baginsky said that chronically diseased children belonged to recuperative places and not to schools. The value of the forest school was extraordinary if only children that were not too ill were admitted. Forest health resorts and forest schools must be kept apart.

Hr. Lennhoff said the kind of institution to be erected, Waldschule or convalescent institution, would depend on the local conditions. Just so much instruction should be given as would prevent children from falling back. The forest school as a school for the less unhealthy children might have a future before it.

Hr. Neufert was of opinion that the two kinds of institution might be erected near together; the main object of the one would be the treatment of disease, that of the other the instruction of unhealthy children.

AUSTRIA.

Vienna, July 1st, 1906.

DEXIOCARDIA AND CYANOSIS.

HOCHSINGER showed a case of right-sided cardia in an infant, æt. 6 months, with peculiar symptoms. This child was the sixth by healthy parents. When born, the whole body was of a damson blue colour and asphyxiated. With artificial breathing, rubbing, &c., the infant was restored to life, but has always suffered from shortness of breath and cough. Up to fourteen days ago the child took its food well and in other respects was normal, but bronchitis and nasal

catarrh brought it to hospital. When the child is at rest the cyanosis is absent, but immediately it awakes the cyanosis appears on fingers, feet, face, and arms. When it cries the whole body is as dark-coloured as a damson.

The pulse is 150—160, tonometer pressure 90 to 100. The cardia is wholly in the right side of the thorax while liver and spleen are in their normal positions, which is unusual in transposition of the heart. It is therefore a simple isolated dexiocardia. The cardiac sounds are clear and healthy when the child is quiet and at rest, but as soon as it begins to cry or is fretful a hissing systolic murmur appears, more audible in the precordial region and apex than at the base. The second tone is louder than the first. Behind the right shoulder the same hissing sound can be heard, and greatest at the lowest part. The trouble seems to lie in the venous apparatus or in the wall of one of the ventricles, or it may be due to a stenosis of one of the arterial ostia.

The Röntgen rays revealed a wider area in breadth, and above, between the second and third intercostal space, the pulmonary artery formed a wide arch as it distended. In the second intercostal space the opening Botalli seemed to be closed.

This widening of the pulmonary artery seemed to be the cause of the increased diastolic sound heard over the sternum. The diagnosis was given as a defect in the ventricular septum with dilatation of the pulmonary artery in a congenital dexiocardia.

RACHITIS LARDA.

Drey showed a case of a seven years' child who was pale, fairly well nourished, and well developed. The girl was the eldest of six sisters, who lived in a house with two rooms badly ventilated. Four months ago the mother observed that the girl walked strangely with bent legs, and two months later she complained of great pain and could not walk to school. It appears that when æt. 2 she was taken to Kassowitz' Clinic, where she was treated for rachitis and according to the mother's story no deformity of bone then existed; the only reason for taking the child there was inability to walk. After the use of six bottles of phosphated cod liver oil, the child quite recovered. No other disease was recorded in its history.

On admission the bones of the head and face were normal, the chest was small and compressed antro-posteriorly. The epiphysis of the ribs were thickened, the spinal column straight, pressure on the symphysis pubis very tender, but most striking of all was the thickening of the distal epiphysis of the radius and ulna with a distinct rachitic hand. The lower extremities had the same distal thickening of the tibia and fibula, with a distinct bending of the former, or crura vara. The abduction of the right leg was limited, and gave great pain, a distinct symptom of initial coxa vara.

Drey agreed with Kassowitz' classification of two forms of rachitis tarda—(*a*) cases of long-standing rachitis gravis with deformity, probably delayed till the second dentition period; (*b*) cases appearing in the adolescent period as those recorded by Bokai and Marsden, which have been designated rachitis adolescentium.

A FOURTEENTH CENTURY PRESCRIPTION.

Dr. Senfeld, of Vienna, has been turning out the alcoves of the University Library in search of Dr. Paul de Sorbait's wit and humour. The following prescription is recorded as the result of a consultation of two leading men of the time:—

R Tabellionem (Notary), j.;
Testes (Witnesses), vij;
Fossores cum liqoribus (Gravediggers), ij;
Vespillonum (Pall-bearers), paria ij.

Adde sacerdotem cum aqua et oleo benedictis, quantum satis et dispone domui tuae: quia morieris.

P.S.

R.F.

HUNGARY.

Budapest, July 1st, 1906.

AT the recent meeting of the Budapest Interhospital Association, Dr. Schmidt read a paper on

PROTECTION AGAINST SUNSTROKE,

in which he dealt with the protection of the tissues of the head, and referred to the various articles generally worn to ward off the direct rays of the sun. The entire skull, inclusive of a thin layer of hairs, he remarked, is permeable for thermic as well as actinic rays. Cerebral tissue is relatively less diathermous, so that the cortex absorbs most of the rays. Anæmic blood is much more diathermous than normal blood, and this explains why patients with malaria are more subject to sunstroke. It is hardly probable that the ultra violet rays cause sunstroke; it seems more likely that the heat and light producing rays are responsible. White skin allows these rays to pass through about twice as readily as negro skin. Straw hats and white caps without lining are a very poor protection, the so-called tropical helmet being a much better safeguard. The value of the various cloths used in the tropics had not yet been decided.

Dr. Donath referred in a paper to some

ELEMENTS OF METABOLISM IN EPILEPSY.

Impressed with the contradictory results reported from analyses of the urine of epileptics he undertook the study of urine during a period of from one and a half to two months in each of five epileptic patients; examinations of a given quantity of the urine eliminated during twenty-four hours being made daily. The diet was so regulated in each case as to establish metabolic equilibrium.

Dr. Donath tabulates his findings as follows: (1) The quantity of urine was normal in the majority of cases; (2) the colour varied from straw-colour to golden; (3) the specific gravity was always high, even when an increased quantity of urine was eliminated; (4) acidity was normal, or slightly below normal; (5) phosphoric acid varied within normal limits; (6) the amount of urea corresponded to that considered as medium by authors in general, but it was less than that which should have been eliminated, with the diet given; (7) the quantity of chlorides was generally above the normal, though at times it reached the normal. No connection was apparent between the variations in these elements of the urine and the occurrence of epileptic seizures. An increase in indican was always seen the day following a seizure. Not the faintest trace of albumin was found after an epileptic seizure, whether this was repeated or not.

Dr. Jordan discussed the question of

TARDY HEREDITARY SYPHILIS.

The symptoms of hereditary (tardy) syphilis are generally manifest at birth or appear within the first two or three months. They are the same as in the acquired disease of adults, but differ in their sequence, and in the regularity of their appearance. In tardy hereditary syphilis, tertiary signs may make appearance as late as the twentieth year. Drl Jordan divides these cases into two classes, viz., where syphilitic manifestations were present in earliest youth and had disappeared with proper treatment, and, secondly, where these late signs gave the first clue of infection. This class is not recognised by many syphilographers, but two undoubted cases are cited. It generally appears as a bilateral affection of the knees, either an arthralgia, a simple chronic hydrops, or a deforming arthritis. It is often extremely difficult to make a diagnosis, but if no direct history is present an antiluetic treatment should be resorted to in all symmetrical cases which resist other measures, especially if there are marked fluctuations in the course. Often the presence of a parenchymatous keratitis will assist the diagnosis.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SIR ALEXANDER RUSSELL SIMPSON.

EMERITUS PROFESSOR SIMPSON'S long and distinguished career has been crowned by the well-merited honour of knighthood, and all his old students must have felt, when they read his name in the list of recipients of the King's Birthday honours, that few have more thoroughly deserved recognition than he. Sir Alexander Simpson retired from the chair of midwifery in the University of Edinburgh a year ago, after having occupied it for thirty-four years. A native of Bathgate, he acted in his younger days as assistant to Goodser and to his uncle, Sir James Simpson, whom he afterwards succeeded. He was an unrivalled operator in gynæcology, and has an encyclopædic knowledge of the literature of his subject. In congratulating Professor Simpson on his well-earned distinction, we may also be allowed to express the hope that he may long be spared to enjoy the leisure and recreation to which his labours in science and education so justly entitle him.

WOMEN GRADUATES AND THE PARLIAMENTARY FRANCHISE.—Counsel was heard on June 27th in the action brought by Miss Margaret Nairn, M.A., and other graduates, against the University Courts of Edinburgh and St. Andrews for declarator that the pursuers. being on the register of the General Council of the University of Edinburgh, were entitled to receive voting papers on the occasion of any future election for a member of Parliament to represent the two Universities. After hearing Counsel, Lord Salvesen made avizandum of the case.

PROFESSOR MCKENDRICK'S VALEDICTORY ADDRESS.—Professor McKendrick delivered a farewell address to the students on June 29th, in which he told his audience the story of how he came to be a physiologist, and sketched the progress of the science during the thirty-five years he has occupied the chair. Even before he studied medicine he had been attracted by the natural sciences, especially physiology. In Edinburgh, the influence of John Goodser intensified his desire to devote himself to the subject, but after graduation he saw no hope of reaching the fairyland of science, and had been compelled to practise in hospitals and dispensaries. In 1868, while resident surgeon in a little hospital in Port William, Hughes Bennett came to see a patient dying in a shooting lodge in Glencoe; he met him there, and the result of the interview was that Bennett took him as assistant in succession to Professor Rutherford, who had just been appointed to King's College. His physiological career thus begun, in due time he returned to Glasgow in 1876, and there the happiest days of his life had been spent. Turning to the progress which physiology had made, it was probable that microscopy had now nearly approached perfection, and it was doubtful whether much more progress would be made along the path of histology. Turning to vivisection, he could not understand how its value could be denied—witness Pawlow's researches—yet he thought its educational importance had been overestimated, and that only very few experiments need be demonstrated to students. In the past too much of the student's time had been taken up on difficult experimental work on the physiology of nerve and muscle, and on relatively unimportant matters of electro-physiology, such as a demonstration of Pfluger's law of contraction and electrotonus. The two departments of physiology in which the greatest advances had been made were our knowledge of nerve paths in the central nervous system, and the subject of internal secretions. The influence of this increase in knowledge was seen in yearly increasing accuracy in the diagnosis of nervous diseases, and in the new light thrown on the functions of special organs and the general economy of the body. There could be little doubt that the progress of the next few decades will be made along the line of physiological chemistry; this was confessedly the most difficult of all branches of investigation. It demanded that the writer should be a trained chemist as well as physiologist, that he should have a thorough grasp of organic chemistry and physics. To make an ideal physiological chemist we would begin with a Roscoe, link to him an Emil Fischer, and weld with these a Kelvin and a Pawlow. When we get a grasp of the chemical processes of the cell we will be near an understanding of the phenomena of life. Professor McKendrick concluded by expressing his satisfaction at the provision of laboratories for experimental psychology—the link between physiology and psychology, and said: "Now I lay down my arms, not as a tired or beaten soldier, but as one who has served his time and wishes to retire in favour of youth and energy and enthusiasm. The evening approaches, and one wishes to have time to work on tasks that are altogether congenial, to meditate on the past, and to search the intellectual horizon with hopeful eyes for the revelations of the future."

ROYAL INFIRMARY, EDINBURGH.—The managers of the Infirmary have under consideration an offer by the Admiralty to transfer to them at a peppercorn rent the Royal Naval Sick quarters at South Queensferry. The buildings are to a large extent new, having been completed only last summer, and are now not required by the Navy, owing to the transference to the south of the training ship "Caledonia." The suggestion is that the buildings might be used as a sanatorium, and that if taken they are to be kept in repair and handed over to the Admiralty at three months' notice if required. The buildings are situated in a healthy part of the county, amid beautiful surroundings. Their distance from Edinburgh will no doubt be a disadvantage, on account of the additional cost this would involve. The matter has been remitted to the House and Medical Committees.

BELFAST.

BRITISH MEDICAL ASSOCIATION.—At the annual meeting of the Ulster branch of the British Medical Association, it was decided to invite the Association to meet in Belfast in 1909 or 1910. The last meeting in Belfast was in 1884, and the last Irish meeting was in Dublin in 1887, so it is quite time that the Association visited Ireland again. The formal invitation will not be given till next year when the proposed president will have to be named, but the general arrangements will no doubt be informally discussed during the year. There is evidently a desire to make the meeting, if held in Belfast, as great a success as possible.

THE RECENT EPIDEMICS AT NEWTOWNARDS.—Attention was called several times last year in this column to the epidemics from which the little town of Newtownards in County Down was suffering. The outcome of these epidemics promises to lead to a better state of things in the sanitation and water supply of the town, which were notoriously deficient. A bill is now before Parliament to authorise the Newtownards Urban District Council to remedy these defects, and the statement made by Mr. Macassey, representing the promoters, showed how badly needed the proposed improvements are. In the town, which has 9,000 inhabitants, there were last year 48 cases of scarlatina, 58 of typhoid, 150 of measles, and many of diphtheria and typhus. Dr. Jamison, the medical officer of health, gave a horrible picture of the state of many houses as regards sanitary matters, and said that for fifteen years he had been urging the necessity of improvement.

QUEEN'S COLLEGE.—On Saturday afternoon, the 30th ult., the College received a visit from its generous benefactor, Sir Donald Currie. It was owing to his munificent gift of £20,000 that the Better Equipment Fund was able to reach the grand total of £70,000, and the fruit of this fund is already visible in the greater efficiency of many of the departments. It was fitting, therefore that on the occasion of his visit to Belfast to receive the freedom of the City, the College should also do Sir Donald Currie honour. He received addresses from the College faculty and from

the students, and in his reply he made a further offer of £1,250 if the students could raise the remainder of a sum of £5,000 for the purchase of athletic grounds.

LETTERS TO THE EDITOR.

HYGIENIC MEASURES AGAINST SYPHILIS.

SIR,—If syphilis be preventable, in God's name let it be prevented. As medical men, we are surely justified in using any conceivable means that will compass so desirable an end. But, of all human measures, we as a nation have rejected the most powerful and direct—namely, that of a stringent Contagious Diseases Act. Owing to the sentimental clamour of a knot of faddists the extermination of syphilis has been postponed by half a century or more. Meanwhile the chief burden of that terrible malady is borne by helpless and innocent women and children, and the springs of public charity are depleted in the attempt to remedy the havoc wrought by noisy sentimentalism.

I am, Sir, yours truly,

A SEAPORT HOSPITAL SURGEON.

"FOR FOES WITHIN ONLY."

SIR,—With reference to the paragraph under above heading on the front page of your issue of June 27th, may I be permitted, as a medical man who has borne the heat and burden of the day, to make a few remarks? Never was a truer word spoken than that which attributes the present well-nigh hopeless plight of the medical profession to the fact that "the disciplinary powers of the General Medical Council are mainly domestic." Think for a moment what a revolution would overtake the medical world were the Council to turn its weapons against the enemy without as well as against offenders within the house. At one blow the whole vast field of illegal medical practice would be reduced to a footing of insecurity, and much of it would disappear forthwith. In other words, legitimate medical practitioners would come into their kingdom, which is at present harried and plundered on every side by quacks and charlatans. So far as we are concerned, I have no hesitation in affirming that one clever scoundrel practising bonesetting or some other form of irregular medical practice will cause more monetary loss to the profession than a hundred petty defaulters of our own cloth, who are too often driven into peccadilloes by the degrading poverty of the learned profession which they have embraced.

Sir, in my humble opinion you are entitled to the warmest thanks of the profession for the outspoken way in which you have not only fearlessly demonstrated the evil but also pointed out the remedy. The present constitution of the General Medical Council I regard as a scandalous anomaly. They are, in effect. an assemblage of aristocrats nominated to defend the privileges of ancient and effete corporations. Their attitude towards the main body of the profession is one of lofty arrogance and contempt. Let us agitate as a self-respecting and much-tried profession for a General Medical Council that shall be elected by ourselves. In that, I firmly believe, lies our only hope for the future.

I am, Sir, yours truly,

A VETERAN.

OUR HOSPITALS.

SIR,—Your correspondent, "R. L." seems to grasp half the truth of a very serious situation. Most general practitioners will agree with him in the assertion that serious injury has been done to them throughout the country by the opening of hospitals to patients who formerly paid their fees. That is the evil arising from indiscriminate charity that forms the greater part of the standing wrong known as "hospital abuse." However, "R.L." does not appear to be doing much to set matters straight when he says: "The reform that must be made in our hospitals is evidently that they must let the patients supply the funds required for their support, and not let them be treated as simple recipients for charity." In other words, he would still let the persons attend hospital, although they have no right to go thither, the only difference being that he would make them pay for their accommodation. That may be a plain and simple reform to the mind of your correspondent, but I confess its logic is not clear to me. So far from the payment of a tax remedying the original offence, it would, to my thinking, increase it a hundredfold. First, it would still the conscience of the mean appropriator of charitable funds. Secondly, it would divert still more money from the income of the general practitioner. Thirdly, it would put more money into the pockets of the hospital charities wherewith to carry on their nefarious campaign against the general practitioner. Words of bitterness these may seem, but they are born of experience.

I am, Sir, yours truly,

AN EAST END PRACTITIONER.

London, E., June 30th, 1906.

OBITUARY.

DR. JOHN WINTER DRYLAND, J.P., OF KETTERING.

DR. JOHN WINTER DRYLAND, J.P., who, since 1859, had been in practice at Kettering, died on Sunday week, June 24th, after a long illness due to heart disease and dropsy. In 1859 Dr. Dryland acquired the practice of the late Mr. Sanderson Wyman, of Kettering, which he gradually developed into one of great extent. In conducting this large practice during late years Dr. Dryland had the able assistance especially in the operative and surgical side, of his son, Dr. Leslie Dryland. Dr. Dryland was born at Newbury, in Berkshire, and began his professional career as an apprentice to Mr. Winter, of Brighton, in 1849, and from thence he passed to Guy's Hospital, where he studied with much diligence, and on leaving Guy's he filled for some time the post of Resident Medical Officer at the Reading Dispensary. At Kettering Dr. Dryland was for many years Health Officer for the town, which had grown rapidly and largely during his residence there. He took great interest in the establishment of the new hospital, to which his son was appointed surgeon, in conjunction with Mr. Roughton, of Kettering.

THOMAS SIBLEY STOTT, M.R.C.S.ENG., L.R.C.P.

WE regret to announce the death of Mr. Thomas Sibley Stott, director of the Animal Vaccine Establishment of the Local Government Board, which occurred on the 24th ult., at his residence in Highgate Road, in his sixty-fourth year. Mr. Stott, who studied at St. Bartholomew's, qualified as M.R.C.S. England, in 1863, and L.R.C.P. and L.S.A. in 1864. Before being appointed director of the Animal Vaccine Establishment he was assistant director under Dr. R. Corry.

HECTOR ALLAN, M.B.,C.M. ABERDEEN.

WHALEY BRIDGE was last week shocked at the sudden death of Dr. Hector Allan, which occurred on the 27th ult. He had resided and practised in Whaley Bridge 32 years, was surgeon-captain in the 2nd V.B. Sherwood Foresters, Notts. and Derby Regiments, and held the long-service medal. He was Medical Officer of Health for the Urban District Council, and public Vaccinator for the district. In politics he was a Liberal. His medical education was conducted at the University of Aberdeen, where he graduated M.B., C.M., in 1870. His death is a great loss to the neighbourhood.

W. BATES RAMSDEN, M.B.,CH.B.VICT., B.Sc.

THE death occurred last week under peculiarly pathetic circumstances, of Mr. William Ramsden. On Friday last, just as he was about to begin his lecture at the Public Health Laboratory, he suddenly fell down dead. Deceased had his medical education at Owens College, Manchester, where he passed a most distinguished career, and took the M.B. with honours in 1903. His death at the early age of 29 cuts short a life full of brilliant promise, as it was already distinguished with early achievement.

MEDICAL NEWS IN BRIEF.

Birthday Honours.

IN the list of new baronets is to be found the name of Christopher Nixon, of Dublin. Sir Christopher was educated in Trinity College, in the Cecilia Street School of Medicine, and in Paris. He has held the Chair of Anatomy and Physiology, is Professor of Medicine at the Catholic University School of Medicine, an ex-President of the Royal College of Physicians, Ireland; member of the General Medical Council, Hon. Fellow of the British Institute of Public Health, a member of the Senate of the Royal University of Ireland, and senior physician to the Mater Misericordiæ Hospital. Sir Christopher was the first President of the Royal Veterinary College, Ireland, an institution which he took an active part in founding. He is the author of several medical treatises, among them being a "Handbook of Hospital Practice and Physical Diagnosis," and various papers on diseases of the heart and the nervous system.

Epsom Medical College.

AT the annual meeting of the Governors of Epsom College, on Thursday last, Sir Constantine Holman, M.D., presiding, the Council presented a report as to the work of the past year, showing that the college gives gratuitously an education of the highest class to 50 necessitous sons of medical men, and provides pensions of £30 a year for 50 medical men, or the widows of those deceased, at a cost of £6,000 yearly. There were now 50 foundation scholars, 10 council exhibitioners, 142 other boarders, 36 boarders in masters' houses, and 16 day boys, making a total of 254. The names of seven successful candidates as pensioners were announced. Out of 30 candidates, four had been successful in obtaining foundation scholarships, viz., Peter M. Braidwood, Arthur Chamberlayne, Robert R. L. Williams, and Geoffrey J. Barrow. The announcement of a donation to the funds by a lady of £5,000 was acknowledged with grateful thanks.

Sir Constantine Holman, on resigning his position of treasurer, which he had occupied for 19 years, said that 51 years ago he took part in the initiation of the college. In 1887, when he became treasurer, there were 191 pupils, as compared with 254 now.

On the motion of Sir William Church (chairman of the Council) the resignation was accepted with regret, and Sir C. Holman's services were warmly acknowledged. He was elected a member of the council, and Mr. Henry Morris was elected treasurer.

Honours to British Research Laboratories.

ALTHOUGH scientific research receives little encouragement in this country, it is gratifying to find that the labours of British scientists are recognised abroad. The Awards to the British Section of the recent Liege Exhibition were distributed at the Mansion House on June 13th, and the following presentations were made:—Wellcome Chemical Research Laboratories, one grand prize, one diploma of honour and two gold medals; Wellcome Physiological Research Laboratories, one grand prize and two gold medals. Medals were also awarded to the respective directors of these institutions.

Women in the Medical Profession.

AT the annual distribution of prizes in connection with the London (Royal Free Hospital) School of Medicine for Women, on Thursday last, under the presidency of Mrs. Garrett-Anderson, M.D., Her Grace the Duchess of Marlborough distributed the prizes and certificates. It was stated that of the large number of students who had passed through the school 43·1 per cent. had taken the London University degree, the highest possible in medical examinations. Only 3·6 per cent. had not qualified at all.

Lady Frances Balfour, who proposed a vote of thanks to the Duchess, made the amusing confession that although for almost a lifetime she had devoted herself to the cause of women doctors she could never bring herself to be attended by one. What, she wondered, would be the result, if Mr. Asquith were told that unless he granted the franchise to them he would be attended by women doctors for the remainder of his life. It might be more effective than storming his citadel.

Dr. Edith Pechey-Phipson, in seconding the proposal, urged her hearers to remember, when they heard of a clever operation or diagnosis by a woman doctor, that they as a sex were classed as lunatics and criminals, a remark that was greeted with cheers and laughter.

West London Hospital Dinner.

THE annual dinner of the West London Hospital and Post-Graduate College was held at the Trocadero Restaurant on June 28th, 1906, under the presidency of Mr. Stephen Paget. After the loyal toasts had been honoured the chairman depicted in glowing terms the future of the hospital, which had now reached the jubilee of its active life. Mr. L. A. Bidwell, Surgeon to the hospital and Dean of the College, in response to the toast of "The Post-Graduate College," stated that he believed last year was almost a record one in the history of any hospital, no less than 226 post-graduates having been enrolled. Constant endeavours were being made to improve the working of the various departments of the college, and he referred with pleasure to the institution of a special section for the study of tropical diseases, which had been placed under the care of Dr. G. C. Low. The health of the chairman was suitably proposed by Dr. G. P. Shuter.

Central Midwives Board.

AT the examinations for certificates of the Central Midwives Board recently concluded, 376 candidates presented themselves, of whom 300 passed; the percentage of failures was 20·2. The women came from all parts of the United Kingdom, almost every training school and maternity hospital being represented; many were also "coached" by private teachers.

Liverpool School of Tropical Medicine.—Anti-malarial Measures in Greece.

THE following telegram has been despatched by the Liverpool School of Tropical Medicine to the King of the Hellenes, Athens, viz.:—"The Liverpool School of Tropical Medicine, at request of the Lake Copais Company, despatched a member of their staff to Greece to investigate malaria there. He reports that malaria is seriously prevalent in Greece, but should be preventable. Sir Alfred Jones, Chairman of the School, of which H.R.H. Princess Christian of Schleswig-Holstein is President) asks whether His Majesty will authorise the School to initiate a movement in England for the prevention of malaria in Greece to co-operate with the Grecian Anti-malarial League of which His Majesty is Patron."

Experiments on Living Animals.

IN the House of Commons last week, Mr. G. Greenwood (L. Peterborough) asked the Home Secretary if his attention had been called to the fact that the recently issued Return of Experiments on Living Animals for the year 1905 shows an increase of no less than 5,373 of such experiments, as compared with the return for 1904, whether he knew any reason to

account for this increase, and whether he could now say when the Commission to inquire into the matter of vivisection would be appointed, and what the terms of reference to this Commission would be.

Mr. Gladstone (Home Secretary).—My hon. friend will see from the return that nearly the whole of the increase in the number of experiments—5,083 out of a total 5,373—is accounted for by the additional inoculations, hypodermic injections, and feeding experiments which have been made. The increase is due to the greater importance attached to biological tests in practical medicine, and to the greater number of these experiments which are performed on behalf of local and other public authorities. With regard to the composition and terms of reference of the proposed Royal Commission, I hope to be able to make an announcement very shortly.

Vital Statistics

ACCORDING to official returns of the Registrar-General, the deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 14·2 per 1000 of their aggregate population, which is estimated at 17,732,694 persons in the middle of this year. Measured by last week's mortality, the highest annual death-rates per 1000 living, were :—From *all causes*, 18·1 in Warrington, 18·2 in Middlesbrough, 18·3 in Bradford, 19 in Belfast, 19·5 in Merthyr Tydfil, 19·8 in Burnley, 20·1 in Dublin, and 2·28 in Hanley; from *measles*, 1·4 in Bradford, 1·6 in Wallasey, 2·2 in Manchester and in Salford, 2·9 in Halifax, and 3·0 in Burnley; from *diphtheria*, 1·2 in Hornsey and 1·6 in Wolverhampton; from whooping-cough, 1·0 in Glasgow, 1·3 in Tottenham, 1·4 in Coventry, and 1·5 in West Bromwich; and from *diarrhœa*, 1·1 in Walsall and in Oldham, 1·3 in Walthamstow, 1·4 in Merthyr Tydfil, and 3·0 in Great Yarmouth. No death from small-pox was registered in any of the large towns.

Spotted Fever in Glasgow.

OWING to the large number of cases of cerebro-spinal meningitis which have occurred in Glasgow during the past three months—in all some 44 cases—the Town Council have decided to hold a special meeting to consider the advisability of including the disease for one year among the infectious diseases which are compulsorily notifiable to the health authorities.

Queen Alexandra Sanatorium

IN the absence of Lord Balfour of Burleigh, who is abroad, Lord Burghclere presided at the third annual general meeting of the Queen Alexandra Sanatorium, Davos. As soon as the necessary amount has been raised the sanatorium will be built upon a site already bought for the purpose near Davos. The sum collected so far according to the report presented on the 27th ult., reaches £13,536, of which close on £500 was subscribed last year. The amount still required is £17,500. Lord Burghclere stated that the plans would accommodate sixty patients. He believed by next spring the building would be commenced in earnest. The estimate of the total cost of the building and furnishing was approximately £22,000.

The Jubilee of the Catholic University School of Medicine.

THE Catholic University School of Medicine in Dublin celebrated its Jubilee last week, amid general congratulations. The festivals consisted of an athletic sports meeting on the 28th ult., a conversazione at the Mansion House on the 29th, and a dinner on the 30th ult. At the dinner about 150 guests sat down under the chairmanship of Sir Christopher Nixon, while in an adjoining room about 200 students dined under the chairmanship of Mr. McArdle.

Dr. Mannix, President of Maynooth College, proposed the only toast of the evening, "The School." Fifty years ago he remarked, the School was founded to vindicate a great principle, and to fight a great cause. In the fifties there were no big endowments to attract students to their University. There was no inherited prestige to confer real or imaginary importance to the teaching given within its walls, but yet the School from the first lived and flourished, and never during its fifty years history was it stronger, more flourishing, more vigorous, and more hopeful than to-day. Their grievance in the Medical School was but part of a larger grievance that kept the people of the country without University education worthy of the name.

Sir Christopher Nixon, Bart., who was cordially greeted, said he would like to say in respect to his own position in regard to the vital University question that he maintained that the question of the University in which they should seek for their degrees was not really such a vital matter, if the means of educating their students were provided in such a way as fully justified their reasonable demands. Whether that University were the University of Dublin, under such conditions of equality as would secure what was involved in the Catholic claim, or the Royal University under the altered conditions proposed in the recommendations of the Commission made very little matter.

Apothecaries' Hall, Ireland.

THE Summer Medical Examinations will commence with the First Professional on Monday, July 16th, 1906. All entries should be made at once with the Registrar, 40 Mary Street, Dublin.

The Royal University of Ireland.

THE following candidates have passed the First Examination in Medicine :—Michael J. Ahern, William F. Algeo, William W. Allison, Harold Black, Francis J. Burke, Sarah E. Calwell, Patrick E. Carroll, Frederick Carson, Louis Cohen, Pierce Cotter, Robert C. Cummins, Thomas A. Daly, Herbert Emerson, Thomas Fitzgerald, Michael J. Fogarty, Philip J. Gaffikin, George S. Glass, B.A., Harry P. Hannigan, Charles A. P. Harrison, William S. Haydock, Timothy F. Hegarty, Daniel Higgins, Thomas H. Houston, Melville C. Irwin, George Jackson, Ignatius P. Kelly, Robert A. Kerr, Thomas J. Kilbride, Patrick D. McCullen, Louis J. E. McHugh, Thomas P. McMurray, Henry P. Malcolm, Michael Moloney, Alfred J. Moran, Henry C. Mulholland, Laurence P. Mulligan, Denis Murphy, Joseph E. O'Sullivan, William Paul, William Prendiville, Thomas Reynolds, James J. Ryan, Gerard Shendan, Charles J. Simpson, John Stephenson, Walter Stevenson, James Stewart (Sch.), Bernard Telger, Samuel J. Turkington, William Turner, Robt. W. Vint, James R. White, Timothy Woulfe.

Trinity College, Dublin.

THE following candidates have passed the Final Medical Examination :—Part I.—William Pearson, Robert E. Wright, George F. Graham and John A. L. Hahn equal, Allman J. Powell, Frederick Stevenson, Henry de C. Dillon, Charles H. O'Rorke, Edward C. Stoney, Richard G. S. Gregg, James C. C. Hogan, Wilfred J. Dunn and Henry J. Keane equal, John W. Lane and William S. Thacker equal, John H. Morton, Edmund H. Sheehan, James E. M'Farlane, Joseph H. Elliott, and Eleanor E. Finegan equal.

Final Medical Examination. Part II.—*Surgery*—John C. P. Beatty, Francis R. Coppinger, Thomas H. Peyton, Edward Gibbon, Lily A. Baker, Thomas L. de Courcy, Henry D. Drennan, George Dougan, Ernest C. Phelan, Ernest C. Crawford, Thomas J. Cobbe, John B. B. Whelan, Ernest D. Caddell.

MEDICAL APPOINTMENTS TO THE POST-OFFICE, GLASGOW.—There is great excitement in medical circles in Glasgow over the appointment of a Medical Officer to the General Post Office. Applicants have been flying to London, and the lives of the local M.P.'s have been by no means rendered happier by the ceaseless importuning they have been subjected to. It has been definitely decided to appoint six medical officers for the City, so that direct personal supervision of the sick may be ensured. Private practice will likewise be permitted.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS.

ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

A Contribution to the Operative Treatment of Puerperal Pyaemia.—Archibald Cuff (*Journ. of Obst. and Gyn.*, May, 1906) says the clinical picture presented, when septic processes dependent upon micro-organisms, generally streptococci, having their seat in the endometrium, spread to and involve the pelvic venous plexuses and the large veins leading from them, is a somewhat varying one. This variation depends, as is always the case in infection, on the site and extent of the structure affected, and on the virulence and quantity of the toxin at work. Illustrative of these variations of virulence the writer mentions the not uncommon condition of "white leg," where the process is limited closely to the affected veins, as an example of the mildest form of vascular infection, and contrasting markedly with this condition is the one presented by what is clinically known as acute puerperal pyæmia. Here virulent micro-organisms invade the veins of the pelvis, and within two or three days produce a condition of the utmost gravity. Between these two extremes we have those cases which, often distinguished by their later onset, their more extended course, and their slower effect upon the general condition of the patient, are described as subacute or chronic pyæmia. The mortality of these chronic cases is also considerable. Bumm, in the Charité Hospital, Berlin, lost nineteen out of twenty-three cases in which an abscess arose in the course of the disease, although cases where abscesses occur are believed to have a better chance of recovery than those which run their course abscess free. Fochier, of Lyons, struck by this undoubted clinical fact, produced abscesses artificially by the subcutaneous injection of turpentine, and though his supposition that such abscesses produced their effect by attracting to themselves micro-organisms has been proved to be wrong—the abscesses being sterile—be the reason what it may, several successful cases have occurred. Removal of the uterus was next advocated, but this in the hands of Freund, Trendelenberg, and Bumm was a failure. Trendelenberg next modified the suggestion, and tied and cut the right internal iliac and the right ovarian veins and saved his patient. More recently, papers by Michel, Bumm, and Hæckel report successes, the procedure adopted being transperitoneal ligature of the thrombosed veins, the internal iliac veins generally, and after them the ovarian veins if necessary. The author then cites a case successfully operated on by himself, in which a rigor occurred two days after delivery; temperature 104°, pulse 126, and respirations 36. There was no uterine tenderness nor foul discharge. Temperature continued high notwithstanding douching and curetting, and fifteen days later a doughy lump, size of fist, not very fixed, was apparent in right broad ligament; temperature 105°, pulse 132, and respirations 26. Twelve days later laparotomy disclosed the mass to consist of thrombosed veins; these were ligatured on the uterine side with strong catgut, a second ligature being placed further out towards pelvic wall, and finally the right ovarian vein, which was thrombosed also, was ligatured half-an- inch from its junction with the vena cava. F.

Therapeutics of Retroversion of the Gravid Uterus—Rizzatti (*Annals of Obstet. and Gyn.*) describes the methods of treatment employed in the clinique of Professor Fabbri, at Modena. Whenever a woman is found to have a retroverted or retroflexed uterus in the early months of pregnancy, attempts are at once made to correct the malposition whether there be symptoms or not. According to Bossi abortion is a much more frequent termination to gravid retroversion than is spontaneous reposition, though the contrary is commonly held. The obstacles to the reposition of a non-adherent uterus are three, viz., gravity, friction, and especially negative pressure below. The author holds that even in non-gravid retroversions, this negative pressure is often a hindrance to reposition. He then gives Fabbri's method. With the patient in the "genu-pectoral position," a catheter is passed into the rectum, and with one or two fingers in the rectum, pressure is made on the fundus, while traction with a forceps is made on the cervix. In many cases the simple entry of air into the rectum with the patient in this position, is all that is necessary. F.

Prevention and Treatment of Puerperal Sepsis in Private Practice.—Stone (*New York Med. Journ.*, June) lays stress on the following points: Asepsis is the principal of obstetric technique. It is to be attained by (1) the use of no antepartum douches unless it is necessary to protect the baby's eyes from a purulent vaginal discharge; (2) sterilisation of external genitals and attendant's hands; (3) no postpartum douches unless specially indicated. Sterile towels are difficult to obtain, but freshly laundered towels dipped in bichloride solution and wrung out dry are good substitutes, and should be placed beneath the hips and round them; shaving the vulva is as important as in other vaginal operations. Separation and eversion of the labia before introducing the examining fingers is important. After delivery the external genitals should be washed frequently by a nurse with hands sterilised as for an operation. The use of rubber gloves is advised, especially for those engaged in general work. If fever appears after labour, the breasts and constipation being excluded, a systematic examination of the genitals should be made, beginning with the perinæum, then wiping away vaginal discharges and inspecting the vagina and cervix. Aseptic treatment of any wounds in these regions by irrigation with normal salt solution is usually efficient. Having ruled out these organs, the interior of the uterus is examined with the fingers while pressing the fundus down firmly. A bacteriological examination of the interior of uterus should be made. Putrid remains of gestation products should be removed digitally or with the aid of a sponge forceps. The rough placental site must not be mistaken for retained decidua. The uterus is then irrigated with hot saline solution. Ergot is given internally to maintain good uterine contraction. If cellulitis or peritonitis is present an ice-bag is applied to the abdomen, and, later, prolonged hot vaginal douches are given to aid absorption of the exudate. If an abscess is present it is opened in the most accessible region; hysterectomy is rarely required. F.

Hebotomic or Symphysiotomy.—Sellheim, Freiburg (*Monats. f. Geb. u. Gyn.*, March, 1906) considers, as the result of anatomical investigations, that severe injuries of the blood vessels, &c., may be prevented during hebotomic, if the operator, when passing Döderlein's needle, keeps as close as possible to the lower surface of the pubic bone. Even though the danger of hæmorrhage after sawing of the bone requires the exercise of great care, still this must not be driven too far, or the enlargement of the pelvis may not be satisfactory. One must not only saw till the bone is divided, but also till there is free room in the soft parts. In every case, before removal of the saw, it is important to see that the two parts of the brim are well separated. The amount of pelvic enlargement is the same after both operations. The equality of the enlargement towards both sides of the pelvis also seems to be the same. On the other hand, three times as much force is required to bring about an equal pelvic

enlargement after subcutaneous hebotomic as after symphysiotomy. So it may be understood that the soft parts, when retained as in the hebotomic, are a great protection against injuries. The principal protection against severe irreparable injuries to the sacro-iliac articulations, during both operations, lies in the ligaments. In the Klinik in Freiburg, after both operations the woman is allowed to deliver herself if possible. In all cases of both operations which have been performed the author has found permanent enlargement of the pelvis. He would not yet like to decide which of the two operations is really the better.

G.

Hæmorrhages from the Female Genital Organs, and their Treatment.—Döderlein, Tübingen (*Deuts. Med. Woch.*, 1905, No. 47), lays special stress upon the great importance of making as careful an investigation as possible into the cause of the hæmorrhage in every case. A bi-manual examination must be made, and, when necessary, the curette, with removal of portion of the cervix and microscopical examination, must be employed. In the first part of the paper he considers specially the climacteric and post-climacteric hæmorrhages. The so-called "return of the periods," that is, hæmorrhage sometime after the menopause, is almost pathognomonic of carcinoma. These post-climacteric hæmorrhages are usuall y irregular, while the climacteric hæmorrhages which arouse suspicion of myomata are evidenced by increase in the quantity and prolongation of the menstrual flow. During the age of sexual maturity, from the fifteenth to the forty-fifth year, nearly all gynæcological affections may be considered causes of hæmorrhage, *e.g.*, malpositions, inflammations, new growths, abortion, tubal pregnancy, &c. Tubal pregnancy, of course, deserves particular attention in making a diagnosis. As regards treatment, Döderlein protests against indiscriminate curettage of the uterus. He reserves the latter for special cases only, and among them he includes particularly fungous endometritis before the menopause. In acute infective processes of the uterus or its neighbourhood, curettage is strongly contra-indicated. It is also dangerous where myomata are present. In cases in which uterine cauterisation is employed, this process must be carried out with great caution. He does not consider it advisable to vaporise the uterus during the child-bearing period. For preclimacteric, and climacteric hæmorrhages in which diseases such as carcinoma, myoma, &c., can be excluded he found vaporisation most useful. In many cases the menopause resulted, and in others the menstruation became regular and no longer excessive.

G.

Cæsarean Section with Fritsch's Transverse Fundal Incision.—The advantages of this incision according to K. v. Simrock (*Centralblatt f. Gyn.*, 1906, No. 23) are as follow: Entrance of liquor amnii, meconium or blood into the abdominal cavity can be more easily prevented. The patient lies with the pelvis high, and consequ ently the fundus uteri occupies the lowest position, and it is impossible, after lifting the uterus out of the abdomen and shutting off the abdominal wound, for the uterine contents to get into the peritoneum. The hæmorrhage from the uterine incision is much smaller and more easy to stop. The technique is simpler. The muscular wall being of uniform thickness at the fundus, the suturing is more readily accomplished. The child is delivered very easily, because it is generally more than half-born spontaneously, owing to the retraction of the uterus over it from the contraction of the cervix and lower uterine segment. The uterus contracts more strongly and more quickly than after the vertical incision, consequently the wound becomes shorter, and the mouths of the vessels are much narrowed, or, perhaps closed. According to statistics the placenta is very rarely situated in the fundus, therefore it is not often encountered in the incision. Further, when Porro's operation is required, the amputation can be done at a higher level than when the vertical incision is employed, and the abdominal incision can also be made higher up and thus a hernia more easily prevented. Among the last thirty-seven Cæsarean sections in the Frauenklinik, Bonn, with this method there was a mortality of 5·55 per cent. When the patients who were septic before the operation are not included the mortality falls to 4·08 per cent. When there is severe hæmorrhage during the operation the cervix and broad ligaments may be compressed, but it is better not to do this, if possible, because it easily produces secondary atony. Strict asepsis, and very careful suturing of the uterus give the best promise of complete healing.

G.

The Entrance into the Tubes of Fluids Injected into the Uterus. — Buttenberg (*Munch. Med. Woch.*, 1905, No. 35) has experimented on dead bodies in order to discover when this is most likely to take place. The negative result of the experiments can be applied to the living organs, because if inert dead tissue could prevent fluid from entering the tubes *a fortiori*, living tissue could do so. The results of the experiments are as follow: By using a return flow catheter the tubes are rarely opened up, but with the ordinary single catheter they are opened in the majority of cases. It is unusual for a large quantity of fluid to gain entrance. When using Braun's syringe in cases where the cervical canal is narrow, fluid is always driven into the tubes when the pressure is high and there is much liquid injected. Low pressure, withdrawal of the fluid and the use of small quantities at a time, nearly always prevent the entrance of fluid into the tubes. It never occurs during treatment of the uterus with solutions applied on swabs.

G.

The Treatment of Mastitis.—Bauer (*Centralbl. f. Gyn.*, 1906, No. 23) has successfully treated twenty cases of mastitis by the hyperæmia produced by suction. The suction bell was applied in each case for five to ten minutes at a time, and then a pause of three minutes was allowed. The duration of this treatment in the early stage is from forty-five to sixty minutes daily. Later, twenty to thirty minutes are sufficient. Between the applications a sterile suspensory bandage is worn. When pus is present an incision ½ to 1 cm. long is made. In early cases the mammæ are normal after three or four days' treatment, and when the pus formation is not very extensive success is attained on an average in from sixteen to twenty days.

The Nose and the Genital Organs. — The close reflex relation between the olfactory and the genital organs has been a subject of observation ever since ancient times, and in our own day a condition called "nasal dysmenorrhœa" has been described, which is said to disappear as the result of suitable treatment applied to the nose. Bearing these facts in mind, Jerusalem and Falkner (*Weinec Wochenschrift*, 1906, No. 15), have devoted some scientific study to the relations between the nose and the genital organs of the female, particularly in regard to parturition. They find that in many cases uterine contractions were stimulated by the application of electrical stimuli to the "genital spot" of the nasal mucous membrane, and that the patients most easily influenced were those who had previously suffered from dysmenorrhœa. The movements produced, however, were less than were easily produced by ordinary means. On the other hand, cocainisation of the nasal mucous membrane gave marked relief to the pains of labour, without interfering in any way with the strength of the uterine contractions. Puerperal after pains were treated with similar effect, a single application of cocaine being in most cases sufficient to abolish the pains. It is possible that these results are due to suggestion, but if suggestion be excluded they seem to promise some practical utility.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

PHYSICAL EXAMINATIONS FOR THE ARMY MEDICAL SERVICE.

A CORRESPONDENT, who is desirous of entering the Army Medical Service, writes to ask us if a defect of the left hand, caused by an accident some months ago, will be a physical disqualification for the service. In reply we would refer him to pages 4 and 5 in the regulations for "Commissions in the Army." A copy of these regulations can be had free on application to the Army Medical Department, 68 Victoria Street, Westminster. As the physical infirmity referred to by our correspondent appears to be slight, we communicated with the Director-General of the Army Medical Service, who informs us that it cannot be determined without examination whether the disability would be considered a disqualification or not, but that our correspondent could have the preliminary medical examination referred to in the regulations.

A BOLTON PRACTITIONER.—Cardiac paracentesis can be carried out with almost perfect safety, provided that rigid asepsis be preserved throughout the operation.

AN EAST-END "POGROM."

AN amusing occurrence is reported from New York, where the Jewish parents of some 6,000 scholars tried to storm the schools. They were under the impression that the wholesale removal of adenoids, to which their children had been subjected, was intended to prevent them speaking Yiddish. The Hebrew race is specially prone to adenoids, but as a rule their intellectual powers are more receptive of new ideas than might be inferred from the foregoing incident.

POISONING BY PHARAOH'S SERPENT.

THE toy known as "Pharaoh's Serpent," formerly in immense vogue, but hardly ever heard of now-a-days, was recently answerable for the death of a child in Nottingham. It consists of a pellet, which on being ignited swells up into a long, bulky, wrinkled ash, somewhat resembling a snake. Its chief active ingredient is mercuric sulphocyanide, a highly poisonous substance that comes under the schedule. On that ground the vendor of the pellets, which were swallowed by the deceased child, is being charged with manslaughter.

THE FASHIONABLE COMPLAINT, APPENDICITIS.

A CORRESPONDENT writes us:—"We have now come to regard 'appendicitis' (especially if we have been fortunate enough to escape death by operation) as a certain passport into the best and most exclusive society! The time is fast coming when a well-bred person will as soon think of carrying about a 'verniform appendix' as he would of leaving stick or umbrella at home when going for a walk."

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 4th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. H. R. Spencer, Dr. H. R. Andrews, Dr. Eden, and Dr. Foulerton. Short communications:—Dr. C. N. Longridge: A Short Note on 64 Cases of Contracted Pelvis.—Dr. H. Williamson: A Case of Adenoma of the Labium Majus. Dr. A. Louis McIlroy: Demonstration with the epidiascope on Primary Cancer of the Ovary.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. M. White: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. C. Watson (Edinburgh): Diet Therapy in the Light of Recent Research, with Special Reference to the Use of Animal Proteid Food (with lantern demonstration).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. F. Taylor: Medicine. 3.15 p.m. Mr. M. Robson: Surgery. 4 p.m. Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

THURSDAY, JULY 5th.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. General Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. C. Watson (Edinburgh): Diet Therapy in the Light of Recent Research, with Special Reference to the Use of Animal Proteid Food (with lantern demonstration).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. G. Rankin: Medicine. 3.15 p.m. Sir W. Bennett: Surgery. 4 p.m. Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Ear and Throat.

FRIDAY, JULY 6th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. E. Waggett. Clinique. (Ear).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. R. Bradford: Medicine. 3.15 p.m. Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Skin.

SATURDAY, JULY 7th.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

Vacancies.

Brompton Hospital Sanatorium, Frimley.—Assistant to the Medical Superintendent. Salary £100 per annum, with board, lodging, attendance, and washing. Applications to the Secretary, Brompton Hospital, London.

City of Nottingham Workhouse Infirmary.—Resident Medical Officer. Salary £130 per annum, with apartments, board, washing, and attendance. Applications to G. Muncaster Howard, Clerk to the Board, Poor Law Offices, Nottingham.

County Lunatic Asylum, Lancaster.—Male Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. Applications to the Director, School of Medicine, Cairo, Egypt.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £75 per year, with apartments and rations. Immediate application to S. J. Leonard, Clerk. (See advt.)

Littlemore Pauper Lunatic Asylum, near Oxford.—Second Assistant Medical Officer. Salary £150 per annum, with furnished rooms in the Asylum, and board. Applications to Thomas M. Davenport, Clerk of the Visiting Committee, County Hall, Oxford.

London Open-Air Sanatorium, Pinewood, Wokingham, Berks.—Assistant Medical Officer. Salary £100 per annum and all found. Applications to the Medical Superintendent.

Royal National Hospital for Consumption, Ireland.—Two Physicians as (1) Resident Medical Officer; (2) Assistant Medical Officer. Salaries £100 and £50 per annum respectively. Immediate application to the Secretary, 13 South Frederick Street, Dublin. (See advt.)

West Ham Union.—Junior Assistant Medical Officer. Salary £140 per annum, together with the usual residential allowances. Applications to the Medical Superintendent at the Infirmary.

Appointments.

CROLL, W. F., M.D.Aberd., Medical Examining Officer to the Steam Fishers' Provident Society, Aberdeen.

GRAHAM, CECIL L., F.R.C.S.Eng., L.R.C.P.Lond., Surgical Registrar to St. Mary's Hospital, Paddington.

HARRISON, P. B., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at the Leeds Public Dispensary.

JOHNSON, L. CAPPER, M.B.Lond. and Vict., Ch.B.Vict., M.R.C.S., L.R.C.P.Lond., Honorary Anæsthetist to the Surgical Department of the Leeds Public Dispensary.

JORDON, ALFRED C., M.D.Cantab., Medical Officer to the Roentgen Ray Department of the Royal Hospital for Diseases of the Chest, City Road.

KENNEDY, J. C., M.B., B.S.Melb., Clinical Assistant to the Chelsea Hospital for Women.

SALMON ARTHUR GUY, M.D., B.S.Lond., L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer of Health for the Bodmin (Cornwall) Rural District.

SOLTAU, ALFRED BERTRAM, M.D.Lond., F.R.C.S., L.R.C.P.Lond., Honorary Physician to the Plymouth Public Dispensary.

STOCKWELL, G. E. ST. CLAIR, M.B., B.C.Cantab., Clinical Assistant to the Leeds Public Dispensary.

Births.

BENNETT.—On June 28th, at Hillcrest, Northwood, the wife of Norman G. Bennett, M.A., M.B., B.C., L.D.S., of 50 Brook Street, Grosvenor Square, London, of a daughter.

COOPER.—On July 2nd, at Fownhope, Surbiton, the wife of Harry Cooper, M.A., M.D., of a son.

HANDFIELD-JONES.—On June 28th, at the Hermitage Box, Wilts, the wife of Ranald Handfield-Jones, M.D., of a daughter (stillborn).

JOHNSON.—On June 29th, at 3 Ellerker Gate, Richmond Hill, Surrey, the wife of John Robert Johnson, M.R.C.S., L.R.C.P., of a daughter.

MUNRO.—On June 30th, at 1 Oriel Villas, Cheltenham, the wife of D. G. McLeod Munro, M.D., M.R.C.P., of a daughter.

STEWARD.—On June 26th, at 125 Harley Street, London, the wife of F. J. Steward, M.S., F.R.C.S., of a son.

Marriages.

COLE—ROBERTS.—On June 27th, at St. Andrew's, Thornhill Square, London, Richard Charles Cole, H.A.C., to Miss Mabel Roberts, daughter of T. Andrew Roberts, M.R.C.S., 85 Richmond Road, London, N.

Deaths.

BRUORTON.—On June 11th, at his residence, Sandfontein, Uitenhage, Cape Colony, after a long illness, William Bruorton, M.R.C.S., L.S.A., late of Yetminster, Dorset, and Hornchurch, Essex.

COOKE.—On June 28th, at Burghfield, Berks, Robert Thomas Elsam Barrington Cooke, F.R.C.S., formerly of Scarborough, aged 78.

SHARPLES.—On June 26th, at Deal, Eleanor House, widow of the late William Sharples, M.R.C.S., of Leamington.

WATTS.—On June 29th, at Fern House, Henstridge, Somerset, suddenly, Lucy Anne, widow of Thomas Watts, M.R.C.S., late of Frampton-on-Severn, Gloucestershire.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, JULY 11, 1906. No. 2.

NOTES AND COMMENTS.

Bone-setters' Certificates.

A WEEK ago we called attention to the cool assurance of a Herbalists' Association in publicly agitating for legislation to render it lawful for them to grant certificates of death. The reader of a paper at Grimsby recently commented on the dangerous modern tendency among business firms, clubs and other bodies to accept the certificates of so-called "bone-setters." From his own experience he was able to assert that certain railway companies and important insurance companies accepted certificates of the kind. Now, as anyone in the world, no matter how ignorant and knavish he may be, has the right to call himself a bone-setter, *ergo*, a certificate signed by a person so styled is no guarantee of any medical or surgical value whatever. The State has guarded the signature of legal medical documents so carefully that it will not even accept as valid the signature of medical men who have become duly qualified, but who have not taken the further voluntary step of registration. Can a State that refuses under such circumstances the certificate of a qualified (but unregistered) practitioner sanction medical certificates signed by persons having no medical qualifications whatever? Clearly, a bone-setter's medical certificate has absolutely no legal standing. This point is perhaps worthy of the attention of the Medical Defence Union.

How the State can Help.

THE Government derives some £3,000,000 annually from the patent medicine stamp duties. The public press and the printers draw an enormous income from the same source. It is hardly likely, therefore, that any of these interests will be readily worked up to the pitch of self-sacrifice involved in the abolition of quackery. In the matter of quack practice much might be done by influencing Government to exercise a stringent control of death certificates. The writer of the paper above quoted, Dr. Westlake, made a practical suggestion that would, if carried out, place a great obstacle in the path of the charlatan. His plan is to appoint a Government official specially to investigate all causes of death arising directly or indirectly from the treatment of unqualified persons. In that way the local prejudice which often prevails in favour of the offender would be counteracted; the popular mind would be educated by the publicity and importance of an official inquiry; and last, but not least, the police would find it less easy to shirk their obvious duty of criminal prosecution. There is little prospect of this excellent proposal bearing fruit. The voice of a medical journal raised in the interest of reform is like that of one crying in the wilderness. Had we a General Medical Council that took an interest in protecting the profession!—but we have not.

West Ham Workhouse Schools.

TROUBLES come apace upon luckless West Ham. The throes of the official inquiry into local Poor-law expenditure and management are still at fever-heat, when a fresh scandal is more than hinted at in a report presented by the Medical Officer of the Workhouse Schools. The condition of the infants' block he characterises as disgraceful in the extreme, 119 children being housed where there is accommodation for 44, with only one small day-room. "Disease has been rife during the past half-year," he adds. "Thirty children have measles. Disease always follows upon gross overcrowding, and I cannot be responsible for what may happen next. How far those in authority are free from blame in allowing a state of affairs to continue where unnecessary suffering is caused to children it is not for me to say." Accepting for the moment the last proposition, we cannot admit that the English Poor-law is so badly organised that it is not the duty of someone to speak out. The responsibility, from our point of view, rests with the Local Government Board, whose inspectors are presumably acquainted with what goes on in workhouses and workhouse schools. The abuses of the West Ham institution, assuming them to be as represented, must have been perfectly well known for a long time to the inspectors. If this matter comes before Parliament, as it should do, we trust that the position and the conduct of the Poor-law inspectors as well as that of the Local Government Board will be fully discussed.

A Curious Oversight.

WELL might the Wolverhampton Coroner remark, at an inquest held on June 29th, "This is the most remarkable case I have ever been called upon to investigate, although I have been here for fourteen years." The whole story reads like one of the ingenious fictions that characterise the work of some of

our modern sensational novelists. The deceased was a bookmaker and cigar merchant of the town, who, in accordance with modern canons of self-respecting tradesmen, was not above accepting hospital relief. Some six or seven weeks before his death, to be exact, on the morning of April 26th, his housekeeper found him "all smothered in blood," which he explained by saying he had had a fall. A medical man was called in, and next day deceased had six fits. Later he went to the Wolverhampton Eye Infirmary in consequence of having lost the sight of one eye. He was afterwards transferred to the General Hospital, and seemed practically cured. He was treated as an out-patient until his death.

The Bullet in the Brain.

THEN came the *post mortem* examination, which revealed a small scar in the right temple, a bullet in two fragments, a fracture of the base of the skull and an abscess of the brain. One fragment of lead had destroyed the optic nerve, and the other had lodged in the brain substance, where it had given rise to an abscess. How came the bullet in the brain? It was shown that deceased was a heavy drinker, and that on the morning, in April, when he was found covered with blood a revolver had been taken out of the bed. On the whole, there can be little doubt that the jury arrived at a correct verdict when they found that deceased committed suicide whilst temporarily insane. The value of a careful independent *post mortem* could hardly be more conclusively shown. The scar in the temple was about half-an-inch in diameter, white "with a black mark." It was partly hidden by the hair, and might readily escape observation. There was a fissure fracture of the bone leading from the perforation. The extraordinary fact remains that this patient, suffering from extensive cerebral injuries of definite traumatic origin, was under various medical men, probably at least half a dozen, who had no suspicion of the real nature of the malady. The case is certainly entitled to rank among the curiosities of medical history. It is calculated to make the flamboyant weaver of novels green with envy—but there it is.

LEADING ARTICLE.

WHAT IS WHISKEY?

ENGLISH law is an institution of which as a nation we may be justly proud. At the same time we are constantly reminded that while as an instrument of precision and of precedent it may be immaculate, that nevertheless its methods are slow, costly and cumbrous, its results often negative and disappointing, and its principles non-progressive. Some, at least, of these less desirable aspects have been abundantly illustrated in the whiskey appeal case. It is estimated that the costs to the two parties concerned must have amounted to any sum from £100,000 to £150,000. Yet no one is a penny the wiser as to the original problem as to whether the word "whiskey" is to connote spirit obtained from the old-fashioned pot still, or the substituted or partly-substituted product of the modern and far cheaper and less desirable patent still. Before any definition can be secured by the public and the distilling trade it is likely that another £150,000 will have to be spent in carrying the appeal to the House of Lords. If it be impossible to settle a question of such obvious public importance, except on terms of the extravagance here indicated, there need be no wonder at the increasing demand on the part of the democracy for reform in law. In the United States these things appear to be better arranged. The American Government, faced with a similar whiskey problem, has laid down an excellent definition to the effect that whiskey is the distilled product of fermented cereal grain properly matured by age. Four years is the minimum time fixed for maturing the spirit. Under this law the whiskey is closely inspected by Government inspectors at every stage of its manufacture. The consumer who wants pure whiskey has simply to see that he buys a bottle bearing the Government stamp. In other words, the Government of his country provides him with a means of distinguishing between pure grain pot still whiskey and substituted inferior spirit. With all the Anglo-Saxon common sense and thoroughness upon which we pride ourselves in the United Kingdom, we have not been hitherto able to fix a legal standard for whiskey. The question of purity of spirit sold for human consumption has a distinct bearing upon the temperance question. The newer and the cheaper the spirit the more is it calculated to cause acute and chronic alcoholism with all its attendant evils to mind and body. That fact has long since been recognised by the man in the street, as well as by scientific investigators, but it has been left to the practical American legislator to say that whiskey shall not be sold under four years of age. We have no hesitation in asserting that were a similar condition enforced in the United Kingdom it would tend to mitigate the evils of intemperance more than any other single conceivable measure. Why should the distillers claim to possess a sort of vested right to sell immature spirit that has been shown to be detrimental to life and health? As a matter of fact, the Government of the country has always been more or less unduly influenced by the preponderance of the brewing and distilling representatives in the legislature. In the interests of temperance, with which the future welfare of the nation is closely interwoven, it is to be hoped that the operations and conditions of the "drink" trade will be rigorously overhauled at no long future period. Viewed in the light of the legal proceeding in the recent whiskey trial, it almost seems that the bringing about of many pressing domestic reforms and advances must be preceded by a preliminary simplification, and, if needs be, modification of our present cumbrous legal administration.

THE Scottish Liberal Members of the House of Commons will entertain Dr. Farquharson at a dinner on Monday next in honour of his appointment as Privy Councillor.

NOTES ON CURRENT TOPICS.

The Annual Election of the Royal College of of Surgeons, England.

THE annual election of members of the Council at the Royal College of Surgeons, England, took place on Thursday last, and resulted in the re-election of Mr. Henry Morris and Mr. Richardson Cross, and the election of Mr. G. A. Wright, of the Owens College, Manchester. The latter was returned at the head of the poll, while the unsuccessful candidates were Mr. Charters Symonds and Mr. Bruce-Clarke. In one respect the election establishes a record, inasmuch as it has been marked by the return of two provincial Fellows. Probably Mr. Cross owes his success to the fact that he has already served one term on the Council; it is the usual custom for the Fellows to vote for a retiring Councillor who seeks re-election. On the other hand the return of Mr. Wright at the head of the poll is an indication that his candidature was ably organised. Much literature it is known was issued in his favour, while he secured the support, as a basis, of the whole of the electorate in the Manchester district. A great deal can be done, as the Association of Fellows proved, in these elections by efficient organisation. We congratulate Mr. Wright upon his success, and the Owens College upon its representative on the Council. Meanwhile, his return, in respect to "College politics," will be of little moment, since "College politics," so far as the Fellows are concerned, is dead; even the meeting of the Fellows, which was formerly always held after the declaration of the poll, was abandoned this year owing to the difficulty of obtaining a quorum, which was the case upon the past two or three occasions. Still, in the days of the activity of the Association of Fellows, much useful work was done at these meetings, as the result of which, among other concessions, the "common room" at the College was granted. But the only further reform for which the Fellows should agitate is that of the election of the President of the College. To the Council has been assigned the privilege of electing the President, whereas this duty should clearly belong to the corporate body of Fellows. The President of the Royal College of Physicians is elected by the general body of Fellows of the College, and so should the President of the Royal College of Surgeons by the Fellows of the latter. But nothing less than an earthquake would be equal to moving the conservative body in Lincoln's Inn Fields to agree to such a concession as this.

Pasteurism and its Critics.

SIR JAMES K. THORNTON, K.C.B., contributes to the July number of the *Humane Review* an article in which he establishes to his own satisfaction the thesis that not only is the Pasteur treatment for hydrophobia inoperative to prevent the disease, but that it actually produces it. The attitude of mind of people who argue in this way is perhaps of more interest to the mental pathologist than to any one else, but it is nevertheless deplorable to find a medical man, who has served his country with distinction, ready to accuse the great mass of his professional brethren either of gross fraud or of gross stupidity. He recounts at second hand several cases in which the Pasteur treatment is alleged either to have been unavailing or to have produced the disease. Having quoted two or three such cases, he remarks that "It is quite evident that these persons died from hydrophobia communicated to them by the Pasteurian anti-rabic treatment." That the Pasteur treatment does not in every case produce the disease is explained as due to the fact that in most cases the virus is so attenuated as to be harmless. Sir James Thornton also thinks well to dispose of "the kindred antitoxin treatment of diphtheria." "Many medical men," he says, "have indeed reported excellent results from the use of antitoxin in diphtheria, but these results were due to the carbolic acid, trikresol, or other preservative, which is always added to the serum." It is hardly necessary to give further examples of Sir James Thornton's methods of reasoning.

A New Pathological Society.

WE understand that a movement is on foot to found a pathological society for Great Britain and Ireland, something on the lines of the existing Anatomical Society. It is intended that it should not in any way interfere with existing local societies, but that it should form a bond of union between pathologists scattered in the different teaching centres of the three countries. Already a number of well-known pathologists, such as Drs. Sims Woodhead, Lorrain Smith, O'Sullivan, Bulloch, Lazarus-Barlow, Ritchie, Walker Hall, have given their adherence to the scheme. It is intended that the society shall be ambulatory, meeting periodically at different centres, and the first meeting is to be held next Saturday at Manchester. An interesting programme has been arranged, and the success of the undertaking seems already assured.

"Dropped Kidney"—Compensation Claim.

THE difficulties that surround claims for compensation for bodily injury are often great. They are familiar to most medical men under the guise of "railway spine," the best cure for which grave condition is the award of a good round sum in damages. Now that working men are amply safe-guarded by the Workmen's Compensation Act against injuries received in the course of their occupation, it behoves medical men to be more than ever cautious with regard to subjective symptoms. It would be adding a hundredfold to the labours of the Courts, for instance, were the validity of claims for dropped or dislocated kidney to be established. Such a case was recently tried in Birmingham, whose citizens have of late been more than once considerably exercised in mind over the "dropped" kidney question. In the County Court, Judge Bray dismissed the plaintiff's application on the ground that, assuming he was

suffering from dropped kidney, in his opinion it was not caused or aggravated by the alleged accidental strain. In view of the extreme obscurity and the many fallacies that surround a diagnosis of dislocated kidney, it certainly seems most unwise to base compensation claims upon any such assumption. On an issue of that kind nothing is easier than to produce an array of opposing medical opinions. To encourage litigation of this kind, therefore, is to risk the law's delays and uncertainties in an exaggerated form, while at the same time the dignity of the medical profession is bound to suffer more or less seriously.

The Herbalists' Charter.

FOR some obscure reason or other a certain class of journalist appears to take a malicious delight in anything that tends to lessen the dignity or encroach upon the rights of the medical profession. In pursuance of this spirit, the *East Anglian Daily Times* announces solemnly that "The doctors are up in arms against the application of the National Association of Medical Herbalists for a charter of incorporation." The petition in favour, it appears, of the charter has been presented to the King in Council, and has been advertised in the *Gazette*, in order that petitions for and against the proposal may be lodged before August 4th next. The attention of the Medical Defence Societies, of the British Medical Association, and of the General Medical Council may be drawn to this extraordinary procedure.

A Street Ambulance Organisation.

LORD CAMPERDOWN'S Committee of the House of Lords has struck out that part of a London County Council's General Powers Bill dealing with a proposed ambulance bill. This is the more to be regretted as the need for such a service was conceded on all sides. For once the City of London joined hands cordially with the London County Council, but objected later on the point of rating. Lord Camperdown promptly interposed to stop counsel for the promoters from proving the desirability of such a service, stating that no doubt could exist on the point. The chief ground for rejection appears to have been that the Council scheme was not sufficiently comprehensive. It is to be hoped that the Metropolis will not be much longer without an efficient system of the kind. A good modern organisation would involve central stations, alarms, telephonic communication, motor ambulances and a trained staff. What is true of London applies to all the great provincial towns, many of which are sorely in need of an efficient ambulance service. For that matter, something of the kind in rural districts would prevent a great amount of needless suffering and injury to life and limb.

Strike of Hospital Staffs.

THE people of Russia appear to be becoming past-masters in the art of strikes. By the concerted action of railwaymen a year or two ago the social and commercial circulation, as it were, of the nation was arrested. By a strike of six days' duration the Seamen's Union were enabled to bring the Minister of the Interior to accept their terms. But all other strikes appear to the imagination as pale and ineffectual before that which is now reported, of the whole of the hospital attendants of Odessa, to the number of 700. It is reported by the special correspondent of a London newspaper that the strikers carried off with them keys, medicaments and stores, while they abandoned 3,000 patients to their fate. It is hardly surprising to learn that this strike is reprobated by the public. Some sort of a parallel might be drawn by picturing a similar desertion of the hospitals in Glasgow, Dublin, Edinburgh, Manchester, or any of our great towns. A strike of the kind in St. Petersburgh, where there is an exceedingly large hospital population, would be terrible to contemplate.

A New Industrial Danger.

A SOMEWHAT sensational announcement was made last week at the Southampton Trade Union Conference. It appears that some months ago a new kind of wood was introduced to replace the boxwood shuttles used in the Lancashire workshops. After a few days the workmen who handled the new shuttles began to show signs of more or less serious sickness, and several of them died. An investigation was then undertaken by Professor Harvey Gibson, Dean of the Faculty of Science in the University of Liverpool. He identified the wood as West African satin-wood, and found that it contained a considerable quantity of alkaloid, which, being soluble in salt solutions, would be readily absorbed by a perspiring skin. Experimentally the substance proved to be an active cardiac poison, causing rapid death when injected into lower animals. The symptoms of poisoning are unofficially stated to be headache, sleepiness, running of the nose and eyes, chronic sneezing, giddiness, faintness and shortness of breath. This fresh industrial risk shows in an interesting way how science can often protect the labourer by laying bare the ultimate causes of disease. The financial importance of the incident will be apparent when we recall the fact that Lancashire supplies not only her own looms, but also those of Germany, Russia and India, so that a threatened strike among the English shuttle-makers would at once paralyse many European centres of industry.

Sewage Effluents in Drinking Water.

INCONSISTENCIES mark the progress of most practical steps in hygiene, in many instances, because of the inertia of public or private vested interests. They are nowhere more glaring than in the case of drinking-water in various parts of the United Kingdom, urban and rural. The Congress of the Royal Institute of Public Health

has more than once called attention to the subject. In their present Irish meeting the President of the Bacteriology Section, Dr. A. E. Moore, read a paper on Dr. Houston's report of the chemical and bacteriological qualities of London water for the six months ending April 30th. After some discussion the meeting unanimously resolved that the sources of drinking water should be above suspicion. The general proposition was followed by the more direct and particular resolution, also unanimous, "That in the opinion of this Congress, sewerage effluent of one town ought not to be taken as the source of supply of water for drinking purposes for another town." Opinions of this kind coming from an authoritative source, may reasonably be regarded as shadows indicative of coming events. Enlightened citizens will not go on drinking diluted sewage for ever, nor will they tolerate for all time the double outrage which first pollutes streams and rivers with sewage, and then sells the contaminated water at a high price to consumers.

The Bee Cure for Rheumatism.

A SO-CALLED "bee cure" for rheumatism has recently been exciting a good deal of attention in the United States. Not long ago one Frank McGlynn formed a theory that the sting of the bee was an antidote for rheumatism. It appears that several years ago he noticed that the chronic rheumatism from which he is a sufferer improved after he had been accidentally stung. When he had another attack he obtained equally good results from the use of the same remedy. Accordingly, in order to demonstrate his method, he permitted himself to be stung by one hundred bees at an apiary near Philadelphia, in the presence of some 2,000 persons who had gathered together to discuss bees and their habits. The action of such an application would be due mainly to violent counter irritation, which would doubtless have a beneficial effect upon most forms of chronic rheumatism. Possibly there might be formic acid or some other chemical agent in the bee-poison of medicinal value. The remedy, however, must be excessively dangerous. In the United Kingdom the sting of a single bee is sometimes attended with swelling and other inflammatory symptoms, of nervous, vascular and septic origin, that may even lead to fatal results. Then, again, it is well known that some persons are more susceptible than others to bee-poison. On the whole McGlynn's remedy appears to belong to that kind which is worse than the disease.

A Curious Medical Election.

CARDIFF is much exercised at the result of a preliminary weeding-out of candidates for the appointment of Medical Superintendent of the local asylum. There were no less than forty-seven applicants, some of them having a most distinguished record. The terms of the advertisement stated that canvassing, direct or indirect, would be a disqualification. It appears, however, that some of the candidates canvassed freely, thus gaining an undue advantage over those who adhered to the conditions. This flagrant violation is no doubt to a great extent answerable for the storm of angry rumours that has since gathered. Under the circumstances the wisest plan would probably be to refer the matter back to the Asylum Committee for reconsideration and further report.

Enteric Fever in an Asylum.

ON the 7th instant it was officially reported to the Metropolitan Asylums Board that on July 2nd there were fifty-five patients and two attendants under treatment for enteric fever at Belmont Asylum, and that seven persons had died of the complaint. Sixty-two uninfected patients had been transferred to a special fever hospital. At the time of report the cause of the outbreak had not been ascertained.

PERSONAL.

DR. J. M. ATKINSON, Principal Civil Medical Officer of Hong Kong, who is at present in England on leave, is returning to the Colony to resume duty next month.

DR. G. A. FINLAYSON has been appointed Pathologist to the Government of the Straits Settlements at Singapore.

AT the recent annual dinner of the Edinburgh Royal Infirmary Residents' Club, Sir Lauder Brunton, the retiring President, was supported by no less than seven of his fellow residents of 1866-67. David Christison, M.D., LL.D., was elected as his successor.

DR. HUGH J. M. PLAYFAIR has been appointed lecturer in Practical Obstetrics to King's College Hospital School.

MR. C. S. LOCH will open a discussion on the Relation of Sanitary Authorities to Charitable Organisations at the annual meeting of the Incorporated Society of Medical Officers to be held at Bath on July 14th.

AT the annual meeting of the Fellows of the Royal College of Surgeons of London, Mr. George A. Wright, of Manchester, was elected at the top of the poll into the Council of the College, while Mr. Henry Morris, of Middlesex Hospital, and Mr. F. Richardson Cross, of Bristol, were re-elected.

MR. DAVID HERON, M.A., St. Andrew's University and University College, London, has just published an interesting paper on national deterioration. His contribution is the first of a series upon the subject which the Department of Applied Mathematics of University College has been enabled to organise, thanks to the generosity of the Drapers' Company.

THE chairman of the Middlesex Sessions last week drew attention to the new Testaments provided for administering the oath. The covers were washable and any danger of microbes was minimised. The covers were of white composition, and the ushers were provided with cloths for the purpose of keeping them clean.

A CLINICAL LECTURE ON CARCINOMA.

Delivered at St. Bartholomew's Hospital, London, on May 23rd, 1906.

By CHARLES BARRETT LOCKWOOD, F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital.

GENTLEMEN,—It occurred to me that some cases of carcinoma at present in the wards would serve as a text for a clinical lecture to-day, and especially as each one of them raises points of very great importance with regard to the disease.

The first patient that I propose to refer to is a compositor. His age has little bearing upon the nature of his disease, excepting that carcinoma, which he has got, is one of the privileges of seniority. You must not, however, suppose that youthful people never suffer from carcinoma. Not infrequently carcinoma of the vermiform appendix has been found in quite young people, and, until microscopically examined, the disease has been supposed to be tuberculous in character. This patient came in with an ulcer at the posterior part of his rectum and anal canal. Some portion of it was removed and microscopically examined, and was found to be a columnar-celled carcinoma undergoing mucoid change. I attach no importance to that, because having watched cancers undergoing mucoid change, and also colloid change, I have not myself observed that it ever indicates any increased degree of malignancy.

This carcinoma was also examined under an anæsthetic before an attempt at removal was made. The examination under an anæsthetic was made, of course, to ascertain the extent of the growth. I should not say that, because the finger cannot be introduced beyond a carcinoma of the rectum, therefore the carcinoma is outside the possibilities of removal. But, obviously, if the surgeon cannot get his finger beyond a carcinoma of the rectum, he must of necessity remain in ignorance of its upward extent, and when an operation is attempted its removal may be found to be impossible. In this particular case, however, the finger easily passed beyond the carcinoma. Furthermore, the finger was unable to detect any enlargement of the glands in the sacral hollow. We, perhaps, hardly expected to find enlarged glands in the sacral hollow, because, as far as we could tell, the carcinoma was not of very long duration, and because we knew that this carcinoma was growing in the interior of his intestinal canal. A carcinoma growing inside the human intestine, or bladder, or stomach, or gall-bladder, is usually a long time in escaping to the exterior, and, in that way, differs from carcinoma of, for instance, the mammary gland, which possesses no capsule, or of the tongue, or the pharynx. This examination under an anæsthetic also showed that the finger could be passed on either side, thus proving that the growth had not extended into the ischio-rectal fossæ. Therefore, it was determined to remove this carcinoma.

But another very important point in the case had to be taken into consideration, because it was found, upon examination, that the patient's urine contained a very considerable amount of sugar, nearly three ounces of sugar in four pints of urine, per diem. That is a very considerable quantity of sugar to lose. Now experience has shown that major operations performed on diabetics are exceedingly dangerous. I remember, some time ago, being called upon to crush a stone for a patient who was found to have 3 per cent. of sugar in his urine. The stone had to be crushed because otherwise the patient could not continue in any way to perform his ordinary duties of life, and, besides, it was quite clear that life was a burden to him. Though seventy years of age, his prostate was but moderately enlarged, and in every other respect he was vigorous and strong. After considerable inquiry and consideration with regard to this case, the conclusion we came to was that, provided the sugar was under control, the operation might be undertaken with a reasonable prospect of success. It was found, when the patient was put on strict diet, and deprived of the sources of sugar, that the sugar almost entirely disappeared from his urine. So that the stone was crushed and the patient did exceedingly well, and in about a week's time was making arrangements for going home. But the weather suddenly turned exceedingly cold, and one day the patient became rather sleepy and very quiet. The next day he became still more sleepy and quiet, and afterwards became comatose and died of his diabetes. I do not know how that calamity could have been very well prevented. We had done all we could. He probably got the condition known as acetonæmia. I believe it is now customary to give people with diabetes, suffering from acetonæmia, considerable quantities of carbonate of soda in their milk or fluid. However, I know from my own personal experience that an operation of moderate severity upon a diabetic is a very perilous proceeding. Moreover, the ordinary septic bacteria are better able to grow and flourish in tissues impregnated with sugar than in the tissues of ordinarily healthy people.

With regard to this patient, whose case we are specially discussing, we set to work to get the amount of sugar in his urine under control, and I think I am right in saying that the amount had been reduced from 1,200 grains before operation to 36 grains after the operation had been performed. The operation was an ordinary straightforward cutting operation, and care was taken to guard against serious infection. After the operation was over the cut surface was dusted with iodoform, a drainage tube was passed into the rectum, and the wound was satisfactorily packed with iodoform gauze. As a result, any septic fluid in the rectum could pass out through the tube, and was not brought into contact with the newly-severed tissues. By the fourth day, when the tube was taken out, the cut surfaces of the wound had become sealed more or less securely by the usual processes of inflammation. The patient never had any serious degree of sepsis or even discomfort after the operation.

Now I come to another point with regard to this man. As I have already told you, when we made our first examination of his rectal growth by the usual microscopic process we found that it was a columnar-celled carcinoma. He has got a carcinoma inside the rectum; he has got the muscular walls of the rectum between it and the tissues on the exterior. That type of carcinoma does not seem very prone to spread along the lymphatics into the neighbouring glands, and that, I think, so far, is favourable for the man. But when we came to examine a large section of the growth we discovered that something else was proceeding. The man has got squamous epithelium in his anal canal, and this squamous epithelium is observed to be growing into his tissues, and the same is true of the columnar epithelium. This is a very striking fact, because he has got two types of carcinoma proceeding in his body at the same time. And these two kinds of carcinoma, I venture to say, are due to one cause. What is that one cause? There is one little point in his clinical history which throws some light upon it. The notes on his clinical history state that in 1898 he had some anal discharge, and had had anal discharge ever since. So that he has had some trouble there for many years. There was a patient in this hospital

who had had a granulating wound for nineteen years, and at last it became cancerous. Another man had an ulcer on the dorsum of his foot, and after twenty years it became cancerous. It would seem that if some people have an open sore long enough something may be planted upon it which makes it cancerous. I suspect that this man has had that sore open for a long time.

Another point: The subcutaneous surface of the anal canal sends its lymph into the lymphatics along Poupart's ligament, and onwards into the femoral canal, and so into the lower pelvic glands. The patient has been felt, to see what the glands of the groin are like, and these glands have been found to be slightly enlarged. They will require careful watching, and should they remain enlarged, and there be the slightest possible sign of their increase, then, in spite of the patient's diabetes, it will be necessary to do a rather considerable operation for their removal. At any rate, one of the large ones will have to be removed and examined there and then, in order to ascertain whether they are inflammatory or whether they contain carcinoma. I never believe that such glands are inflammatory until I have seen them.

Leaving that case, which, you may observe, raises many important points, I will pass on to another. This is a man who had quite an ordinary history. One day, he said he felt he must spit a little more than he had been accustomed to. Then at last he felt a sore and painful lump at the back of his tongue. Eventually an ulcer appeared there, and he came to this hospital with a tumour at the back of his tongue, containing a small irregular ulcer in its centre. For clinical purposes we may divide the tongue into thirds—the anterior, middle, and posterior thirds. I saw this man's tongue and felt the lump, and I saw that this lump had degenerated and ulcerated, and I began to think that it was certainly a carcinoma. The history stated that the patient had had that growth for three months. The carcinoma, if it was carcinoma, was not very large. But I have already said that if a person has carcinoma in any organ which does not possess a well-marked capsule, it will spread with extraordinary rapidity into the neighbouring lymphatic glands. Therefore, it became necessary to investigate these. To ascertain the condition of the lymphatic glands, it is, of course, essential that you should know where to find them. The lymphatic glands of the tongue—as described in a lecture which I delivered in this theatre, in 1904, and which was published in the June number of the *Clinical Journal*—are rather curious. You cannot reason about lymphatics at all; you can only observe the course of lymphatics. Nor is it at all easy to ascertain the course of lymphatics by a method of squirting fluids into the lymphatic glands and the lymphatic channels. To my mind, the results of disease are very much clearer if these results are supplemented by certain methods of injection. I will make a diagram of the tongue on the blackboard, with the posterior pillars of the fauces, and the lower jaw, and will divide the tongue into thirds. The lymphatics of the tip of the tongue open into the glands underneath the jaw. Now, if a patient has an epithelioma, as we not infrequently see, at the tip of the tongue, do not forget to feel underneath the mental processes of his jaw for the lymphatic glands there. The lymphatics of the middle tongue open into the glands in the floor of the mouth. These glands are certain to be overlooked if not correctly felt for. If you put one finger inside, and another outside, the mouth, you will feel the glands slipping beneath your fingers. These glands open into the sub-maxillary lymphatic glands, and in cases of carcinoma of the tongue, it may be wise to remove the whole of the sub-maxillary salivary gland for fear of leaving infected glands in its centre.

Now there is a trap into which we may fall. Here (illustrated on blackboard) is the man's neck, and the cricoid cartilage, and the lymphatic glands coming down the neck. In an operation to take away these glands it is necessary to make an incision which will go to the symphysis of the jaw, and thence down to the level of the cricoid cartilage, because the lymphatics of the middle third of the tongue often run straight down the neck to the cricoid gland. In the case of this man, the carcinoma is situated in the posterior third of his tongue. The lymphatics here pass down into the glands over the carotid artery. We sought for enlarged glands underneath the angle of the jaw, over the carotid vessels. The patient confessed to having drunk two quarts of beer a day, so that he is well supplied with adipose tissue. But I thought I could feel an enlarged gland underneath the angle of the jaw. Perhaps I was a little more dexterous at the feeling than some, and rolled that gland a little more skilfully under the tip of an assiduously trained index finger. However, we found enlarged glands under the angle of the jaw, and a series of enlarged glands over the carotid vessels. These glands were found to contain carcinoma, and also a huge mass of squamous epithelium, exactly like what you might have seen growing into the tongue. I am very anxious about the future of this man, and I will tell you why. There is his tonsil (illustrated on blackboard), and surrounded with lymphatics. The lymphatics around the carcinoma may have got into his tonsil lymphatics, and thence infected those in front of the vertebral column.

The lymphatics of the tongue have another peculiarity. Here (represented) is the tongue, and here is the lymphatic network across the dorsum of the tongue, and which carries lymph from one side of the tongue to another. I remember a lady patient who had a similar carcinoma removed from the left side of the tongue, and she did perfectly well for some time. But, a year afterwards, she came back, and then she was found to have got a carcinoma in the right side of her neck, in the glands underneath the right angle of her jaw. The infection had passed back over the dorsum of her tongue and thence found its way into the lymphatics of her neck. This man has not got a very pleasant future before him. With this in my mind I removed half of his tongue down to the epiglottis, and the lower anterior pillars of his fauces. It was worth his while to take considerable risk, in the hopes of obtaining future safety. So much for that man.

I am coming to another case operated upon a short time ago. This is a woman, and she raises another very important question concerning the spread of carcinoma, and, incidentally, concerning the proper methods of operating for it. In August of last year, a very stout woman was sent up from Hampshire with carcinoma of the left breast. I believe I am right in saying that she had had the carcinoma for at least two years, and the medical man who sent her up wrote to me at the time to explain that it was not his fault that the case had been allowed to proceed so far. I did the usual operation and removed, I trust, the whole mammary gland, which is a huge structure, as you are aware, and both pectoral muscles, and also did my best to remove all the axillary fascia and lymphatics. I went above and below the upper part of the axillary vein, and I think I left no trace of carcinoma below the clavicle. We had no reason to suppose, from our clinical examination, that there was any trace of carcinoma above the clavicle, though, of course, neither I nor you, nor anybody else would for one moment imagine that the clavicle is the slightest bar to the spread of carcinoma into the neck.

Now comes the next act in this drama. Not long since the patient returned, and it was quite easy then to feel an enlargement of the lymphatic glands in the posterior triangle of the neck. The carcinoma had obviously spread into the lymphatic glands there. How did it spread to these glands? It might have spread in several ways. One of its methods of spreading must have been this: Here (sketched on blackboard) in the clavicle, here the axillary vessels, and here the mammary gland. One way for the lymph

to flow is by passing underneath the greater and lesser pectoral muscles, and then onwards into the axillary glands, and upwards, over and under the vein into the glands of the posterior triangle of the neck. I suppose that is the usual way in which it flows, but that is not the only way. The lymphatic channels do not always take the longest route; not infrequently they take the shortest. In the case of the mammary gland there are lymphatics which pass from the mammary gland along the suspensory ligaments of that gland over the clavicle, into the subclavian glands, without going through the axillary glands at all. A patient, I remember, came back after having had her breast removed, and she had got an enlarged lymphatic gland, but in a very unusual place—in the upper thorax, underneath the sternomastoid. The cancerous lymph in that case did not go underneath the clavicle, because it then ought to have affected the subclavian glands themselves. I cannot help thinking that the lymph went straight upwards from the breast into the lymphatics underneath the sternomastoid. With regard to the patient whose case we are particularly considering, the enlarged lymphatic glands found in the posterior triangle of the neck were removed, and then it was found that she had got other lymphatic glands, which had been neither felt nor seen, underneath the sternomastoid. With some trouble these glands were also removed. I did not see the thoracic duct, but obviously that was not a very pleasant place to endeavour to remove adherent glands from.

Now the question is, Ought not I to have been rather wiser when first operating, and to have said to myself, "Here is a very stout woman who has a carcinoma which is known to have existed two years in the left mammary gland, and who is known to have considerable enlargement of the lymphatics in her armpit and axilla? Would not it be wise to carry the incision up through the clavicle and the posterior triangle of the neck, and see what the condition of the subclavian glands is, because you cannot see them through the skin?" And with regard to the lymphatics below the sternomastoid, you cannot feel them, especially if the patient is exceedingly fat, as this woman was. I am sure I ought to have done that. The omission of that precaution must very much have shortened this patient's days. I am getting to this stage of my thinking about carcinoma of the breast and indeed of all other regions—that it is becoming more and more necessary not to believe you can feel enlarged lymphatic glands, but to carry out an exploratory operation to see what is the matter with them. What a great comfort it must be to a patient, after the operation is over, to know that the lymphatic glands have been properly looked at, and that nothing has been found in them! You will find on the table a series of sections representing the cases that we have been speaking about, and I advise you very strongly to look at them all, because the time is rapidly coming when the surgeon will have to be able to look at microscopical sections and form his opinion finally upon them. Those who have not practised assiduously in this direction will be taken at a great disadvantage.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Professor C. Yelverton Pearson, F.R.C.S., F.R.U.I., Professor of Surgery in Queen's College, Cork, "On Psoas Abscess: its Nature and Treatment," with notes of an illustrative case.*

AMONG the victims of a motor-car accident last week, near Hastings, we regret to find the name of Miss Ransford, Matron of the Buchanan Hospital, Hastings, who was killed on the spot. At the same time Nurse Minnie had both legs broken.

HUMANITARIAN.—Flogging for robbery with violence has greatly decreased of late years. A similar observation applies to flogging for breaches of prison discipline.

ORIGINAL PAPERS.

UNCOMPLICATED CHOLELITHIASIS: ITS MEDICAL TREATMENT.*

BY WILLIAM BAIN, M.D., M.R.C.P.LOND.

POST MORTEM records show that the presence of gall stones is often unrecognised during life. In some instances gall stones do not produce any definable symptoms, and it also occasionally happens that gall bladder symptoms are ascribed to some other organ. It is well known that in many of the cases that fall into the hands of the surgeon the patients have complained of indigestion for years, and as a corollary to this I may express my conviction that the disease is more common than known-cases indicate. Of the last 100 patients seen by me this year, 12 were cases of cholelithiasis—a large percentage, even for a health resort.

Before discussing treatment it will be convenient to glance at the pathology and symptoms of gall stone disease. It is generally admitted now that gall stones are the result of microbic infection of the gall bladder. The chief inciters of the inflammatory process are the bacillus communis, bacillus typhosus, staphylococcus albus and aureus, and the streptococcus pyogenes. Generally speaking, bacteriological examination shows the presence of only one micro-organism, but mixed infection is not uncommon. The gall bladder may be infected by: (1) the portal vessels; (2) the duodenum, and common duct, or (3) by the general circulation. The first important advance in the pathology of the affection was the production, experimentally, of gall stones by Gilbert and Fournier. To produce gall stones experimentally it was found that the degree of cholecystitis set up must be mild and that the organisms must be retained in the gall bladder for a short period. Moderately severe inflammation causing extensive structural alteration of the mucous membrane prevented the over-production of cholesterin and bilirubin calcium, which are, of course, essential to the formation of gall stones. The varying composition of gall stones points to differences in their mode of development. It is difficult to believe that the cholesterin and bilirubin calcium calculi are evolved by the same process. The cholesterin of gall stones is most probably derived from the desquamation and degeneration of the epithelial cells of the gall bladder. An interesting feature of these calculi is the re-crystallisation of cholesterin that takes place in the interstices of the stone—a phenomenon to which Meckel called attention. Regarding the deposition of bilirubin calcium, the acid mucin is probably combined with calcium and in catarrhal conditions of the mucous membrane it is likely that an increase in the calcium salts of the cystic bile occurs.

The significance of biliary stasis in the formation of gall stones was pointed out long ago. Modern authors regard it as the most important predisposing cause. The factors which favour the stagnation of bile are:—Too little exercise, tight lacing, stooping over desks, excessive eating or drinking by inducing duodenal catarrh, constipation, too long intervals between meals, pregnancy, Glenard's disease, cardiac disease, &c

What are the symptoms and signs of gall stone disease? It is very important that the affection should be recognised early, otherwise medical treatment may not be of much avail. The most frequent symptoms are indigestion, mental depression, irritability of temper, and a sensation of heaviness or discomfort in the right hypochondriac region. The physical signs are tenderness on pressure over the gall bladder and Boas' sign—that is tenderness on pressure in the right subscapular region. There may also be a slight enlargement of the liver and a sense of fulness in the gall bladder area; in some instances, a tumour is felt. When there is a definite history of biliary colic there can be no difficulty in diagnosing the

* Read at the Therapeutical Society.

condition, but some gall stone cases never had colic. In the absence of biliary colic we must rely on palpation for its recognition. I attach some importance to the method by which palpation is carried out. The plan I adopt is this: The hand is first placed immediately beneath the ribs on the right side of the abdomen, and the patient told to breathe quietly for a minute or two. It will be found that the hand sinks deeper in the abdomen with each expiration, so that the presence of a tumour or a tender spot will easily be detected unless the patient is very stout. The same process is repeated on the left side. If the right side is tender further investigation is unnecessary. Gall bladder tenderness must be differentiatcd from that due to the liver. If due to the liver the tenderness can be elicited along the lower border of that organ; if depending upon the gall bladder it is circumscribed. Further, the tenderness of the gall bladder is as a rule greater than that of the liver. By hooking the fingers underneath the right costal arch about an inch from the middle line, and asking the patient to take a deep breath, if the gall bladder is very tender inspiration suddenly stops when the organ comes into cotact with the examining fingers. The sensation produced by pressure over a sensitive gall bladder is testicular and radiating in character, at any rate, two of my patients so described it.

TREATMENT.

The treatment of biliary colic need not be discussed.

The treatment of gall stones may be considered under three heads:—

1.—General factors.
2.—Health resorts.
3.—Drugs.

In the general treatment are comprised suitable food, exercise, and clothing. The diet should, of course, be within the limits of the patient's digestive capability. A mixed diet is the best. A purely vegetarian diet is apt to produce fermentation. A fair amount of animal food is distinctly indicated in this affection, for it is well known that the bile salts tend to keep cholesterin in solution, and an increase in bile salts can be secured by a generous allowance of nitrogenous food. The all-important object is, however, to prevent or alleviate indigestion. The bowels should be evacuated daily. Exercise tells largely in the treatment. For elderly women walking or riding and respiratory exercises are the best, and for middle-aged men riding or golf. Chill should be guarded against. By lowering the resistance of the tissues it may lead to fresh activity of the invading micro-organisms.

The success of health resorts in the treatment of these cases depends upon a number of agencies: (1) diet; (2) exercise; (3) the daily cleansing out of the alimentary tract by aperient waters; (4) the flushing out of the tissues by saline fluid; (6) the soothing action of packs on the affected organ; and (7) mental repose.

DRUGS.

A great number of drugs have been tried to promote the dissolution of biliary calculi. The olive oil treatment is very ancient and has been advocated in most European countries. The experiments of Brockbank gave it a distinct fillip. He found from laboratory experiments that olive oil, oleic acid and sapo animalis dissolved biliary calculi in a few days. So does alcohol, but no one has ever recommended it in the treatment of gall stones. On the contrary, it is rightly vetoed. Among other drugs may be mentioned salicylate of sodium, salicin and benzoate of sodium, oleate of sodium, succinate of iron, calomel, salol and Durande's mixture, consisting of chloroform ether and turpentine. Recently some one recommended acetozone. Some practitioners believe in succinate of iron, but most men I find pin their faith to olive oil. Herter, discussing the drug treatment in 1903, said that "few facts have as yet emerged from the nebulous region of gall stone therapeutics."

Two years ago I began a series of experiments in the hope of finding a remedy for cholelithiasis. The method adopted was as follows:—After the animal was anæsthetised, the skin of the abdomen was prepared and a median incision, 2 or 3 ins. long, was made from the xyphoid downwards. The gall bladder was drawn forwards and held by Spencer Wells' forceps. It was then incised, the bills soaked up, and the stones inserted. Sutures were applied in the usual way, and in a majority of the experiments the gall bladder was stitched to the abdominal wall; in others it was dropped back into the abdominal cavity. When we wished to set up cholecystitis, a culture of the bacillus coli communis in normal saline was injected into the gall bladder before the last stitch was inserted. The mucous membrane of the gall bladder was gently scraped just before the stones were introduced, so as to aid the action of the micro-organisms.

A paper based on these experiments was published in the *British Medical Journal* last August. The following is a summary of the results:—

"(1) That gall stones introduced into a normal gall bladder become dissolved in a comparatively short time—about eight or nine weeks.

"(2) That when a mild degree of cholecystitis is set up gall stones inserted into the gall bladder do not disappear, although there is always a reduction in weight.

"(3) That ichthoform, cholelysin, olive oil, and calomel do not appear to have any effect in resolving calculi introduced into a gall bladder the mucous membrane of which is inflamed.

"(4) That during a course of the Harrogate old sulphur water gall stones become disintegrated in cases of cholecystitis experimentally induced.

"(5) That in the treatment of artificially produced cholecystitis a mixture of urotropin and iridin has a pronounced effect in causing dissolution of the calculi.

"(6) That in regard to the action of barium chloride further experiments are necessary to determine its *role* in experimentally produced cholelithiasis."

As a result of these experiments the plan I generally follow in treating patients is this:—I order a pint of the old sulphur water before breakfast and two tabloids of urotropin and iridin (5 grs. and 1) during the day. With each tabloid a glass of water should be taken, otherwise irritability of the bladder may ensue. In addition, a digestive aid, such as papain or pepsin, is frequently prescribed. Diet and exercise, too, receive careful attention. Mustard bran packs over the affected organ are very effective in diminishing the sensitiveness of the gall bladder.

Three of the patients so treated returned last month to be re-examined. One of these a lady, æt. 69, had been out of sorts for some years. She complained of indigestion and mental depression, and had lost flesh. On examination the gall bladder was found to be very tender on pressure. She could only stay ten days, but continued the urotropin and iridin for over two months at home. At her second visit she expressed herself as feeling perfectly well and had gained in weight. The tenderness over the gall bladder had completely disappeared. The result in the other two cases was equally good. I believe that in recent gall stone disease due to the typhoid bacillus, urotropin is a specific. If the condition has existed for a long time and the walls of the gall bladder largely converted into fibrous tissue, nothing short of surgical interference is effective.

MODIFIED METHOD FOR CURE OF ADVANCED STRANGULATED HERNIA.

By MICHAEL AMBROSE.
Assistant Surgeon, County Mayo Infirmary.

ON reading the different surgical text-books and literature on the subject of hernia during the past decade, one would imagine that the various procedures for "radical cure" had been exhausted

and that the profession was on a sure footing in declaring the twentieth century surgeon to be incapable of producing anything new on the subject. Regardless of such facts, hernia, like our mutual friend, the appendix, forms a field for useful and instructive literature in each successive year and adding procedures, one of which I mean to detail to you, for which, on recognising the frequency of the malady and being unable to find such a procedure already published, I ask no pardon.

On the morning of May 7th, 1906, T.G., a workman, æt. 30, and subject to epileptic seizures, was brought from one of the union infirmaries with the following history :—He received an injury some five years ago which resulted in an oblique inguinal hernia of the acquired type, and on seeking medical advice was supplied with a well-fitting truss with which he was able to perform manual labour without any inconvenience whatsoever. However, on the morning of May 2nd he forgot to put on his truss, and when engaged digging in the garden about three o'clock p.m. he was seized with a violent pain, followed some time after by vomiting, and had to be brought home to await the arrival of the local medical man, who came immediately, diagnosed strangulation, applied unsuccessful taxis, recommended immediate operation, and had him removed as soon as possible to the union infirmary, where taxis was again employed with similar results, from where he was transferred to my care on the fifth day of strangulation, in a condition of fever, vomiting and constipation (nothing but flatus coming away on administering the usual enema before operation), with deap-seated pain over the site of a left-sided strangulated inguinal hernia. In fact, if asked to sum up the symptoms on admission to hospital, I would say strangulation *plus* local peritonitis. Unfortunately, immediate operation had to be delayed owing to a return of the patient's old malady in the form of *grand mal* ;

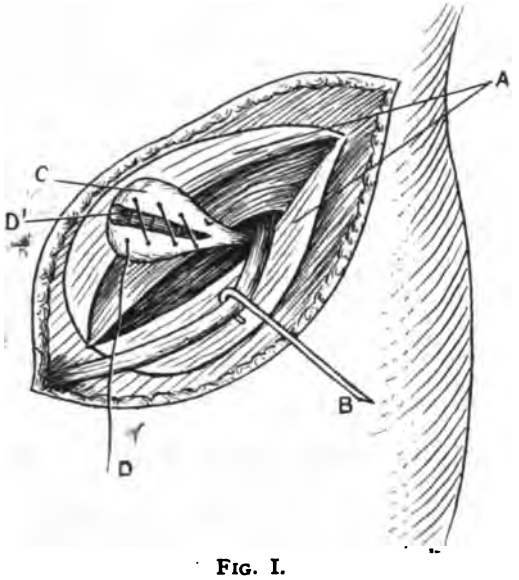

FIG. I.

A.—Divided portions of ex-oblique aponeurosis.
B.—Retractor holding aside and downwards spermatic cord.
C.—Sac opened and empty of contents.
D.—Continuous catgut suture closing sac, but leaving an opening D' near top.

nevertheless, I performed the following the same evening :—

I first did the usual procedure for relief of strangulation, and on opening the sac a quantity of extremely foul-smelling pus made its discharge, revealing an intestine of a deep claret colour, which latter underwent very little change on establishment of circulation, leaving me to believe the gut to be in a very doubtful condition.

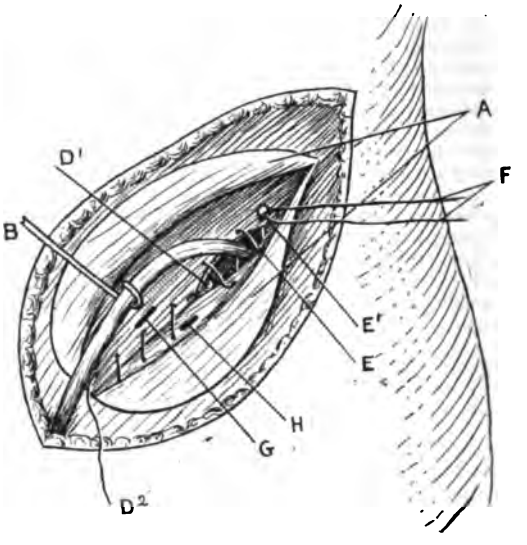

FIG. II.

A.—Same as Fig. I.
B.—Same as Fig. I., but cord in this case pulled upwards.
D'.—Open end of sac showing at top of sutured conjoined tendon (C') and Poupart's (H)
D².—Direct continuation of suture D, Fig. I.
E.—Catgut suture above opening of sac to fix sac and secure radical cure with loop E' on end of same when tightened (shown loose in figure for illustrative purpose).
F.—Silk thread passed through E' for drainage.

Nevertheless, owing to the delay of such procedure as resection when one had to consider the extreme collapse of the patient, and, on the other hand, that I have always regarded an artificial anus a far worse evil than the various complaints for which it is used as a relief, I decided on adopting a modified method and returned the bowel to the abdomen after copious antiseptic lavage of the sac and its contents.

The method consisted of a radical cure, and at the same time allowed drainage from the inflamed sac and bowel, so as to prevent secondary troubles, such as continued local or, what I feared most of all, general peritonitis. I had no need to fix the bowel, as owing to its inflamed and paralysed state it could not change its position (especially if some opium be subsequently administered).

So I turned my attention to the sac, which I sutured with a continuous catgut, leaving a small opening near the top. (Fig. 1.) I next passed the end of my suture through the anterior face of the conjoined tendon beneath the cord and through Poupart's ligament on the outer side, inserting three other stitches with the same suture as in Bassini's operation, with the exception that in this case I used a continuous suture during the whole process, and having the open end of sac,

now twisted on its long axis yet free enough to allow drainage from its interior through an opening about the size of a large pill, visible at the site of outlet of the cord. (Fig. 2.) My next step was to insert another catgut suture above the cord, passing the stitch first through the upper side of the sac near its opening in order to fix latter and secure the radical procedure, as we all know recurrence is not uncommon at this spot. To act as a guide to drainage to the opening in sac I passed a stout silk thread through a loop at end of catgut suture, leaving the former protruding through the sutured oblique muscles and skin on completing my operation according to Bassini. (Fig. 2.) As to after-treatment, I dressed the wound with warm boric stupes for the first four or five days, a quantity of foul discharge coming away, at the end of which time the discharge ceased, enabling me to take away the protruding silk thread by pulling on one end so as to free it from the loop of catgut. The open wound healed from the bottom by granulation, which latter insured against a recurrence of hernia at this the most liable spot; and the skin healed by first intention, with the result that the patient left hospital before the end of the month cured from his hernia and to-day is doing his usual manual work without a truss and suffering no inconvenience whatsoever.

In conclusion, allow me to tabulate the following items of interest :—

1. The delayed operation for relief of strangulation combined with excessive taxis produced acute local peritonitis.

2. Owing to the septic state of sac and its contents, it was desirable to establish free drainage in order to prevent further peritoneal complications.

3. Instead of leaving over the radical cure to some later date and establishing free drainage, as is usually resorted to in such cases, I combined the two methods by the procedure and with the results that I have detailed.

PULSE TENSION: ITS CLINICAL SIGNIFICANCE.*

BY H. W. SYERS, M.A., M.D.CANTAB.,
Physician to the Great Northern Central Hospital.

PART I.

GENTLEMEN,—The subject I have chosen for this evening's address is one of great and increasing importance, and this both as regards diagnosis and treatment. It is now perfectly clear that undue arterial tension is one of the most efficient causes of vascular degeneration, and the increased attention of the present day devoted to blood pressure observations has rendered it evident that alterations of tension occur in many and various morbid conditions, so that it becomes of paramount importance to determine whether or no abnormalities of arterial pressure are present in a given case.

Up to quite lately it has been the custom to gauge the blood pressure by the aid of the finger placed upon the radial artery; there can be no doubt that much valuable information as regards not merely the blood pressure, but also the condition of the wall of the vessel can be gained in this way. But it is obvious that accuracy and precision are not to be looked for by the adoption of this rough and ready method. For the satisfactory estimation of the arterial pressure instrumental assistance is essential. The instrument I have always used is the Riva-Rocci sphygmomanometer as modified by Mr. L. Mummery, and it is very easy to use this instrument the arrangement of which is well adapted for clinical purposes.

As I have just observed, much more attention than heretofore has of late been devoted to the subject of blood pressure and arterial disease. It would seem that to this cause, and not perhaps to any real increase in the occurrence of vascular disease is due the fact that arterial degeneration is much more often diagnosed than was formerly the case. However this may be, it is certain that disease of the arteries occupies at the present time a far more prominent place in the nosology than at any previous period.

Arterial degeneration may affect the aorta or peripheral vessels, or both; very often the aorta is alone involved. It is extremely important to be aware of the capricious manner in which arterial degeneration may be distributed; the circle of Willis may be in an advanced stage of disorganisation, yet the aorta and peripheral vessels may not display the least evidence of disease. When the aorta is involved it is very often the case that the lesion is limited to the arch of the vessel, terminating as it does more or less abruptly at the commencement of the descending thoracic or abdominal aorta. As a working rule, it may, I think, be assumed that when the temporal artery is thickened and tortuous so as to be readily perceptible to sight and touch, there can be little or no doubt that the cerebral arteries are in a similarly degenerated condition. At least the after history of patients presenting this abnormality is very often indeed that of cerebral hæmorrhage, either terminating fatally, or leading to hemiplegia.

In this connection it is of some clinical importance to examine the dorsalis pedis artery; it is sometimes the caset hat this vessel may be found to be more or less degenerate when the radial artery appears to be normal. In doubtful cases it is advisable not to forget this point.

It is of course the case that arterial degeneration is accompanied with increase of arterial tension, but the latter may be met with in the absence of those degenerative changes to which I have just referred. There can be little doubt that the persistence of high arterial tension, by abolishing the elasticity of the wall of the vessel, ultimately leads to the production of those degenerative changes which are so often met with in the arteries at *post mortem* examinations. The two conditions of high tension and degeneration of the arterial wall are connected by the closest ties, being indeed cause and effect.

This being so, it is obviously of the greatest importance to detect the tendency to high tension at the earliest possible moment, and to endeavour by every available means to bring about a more healthy condition of the arterial system.

I propose, this evening, however, imperfectly, to deal with the causation and treatment of this abnormal arterial pressure, and to consider the question of its relationship to other maladies.

And in the first place what is the cause of that arterial tension which is so often met with at the present day in middle and advancing life? I have long been convinced that the tendency to high tension and arterial disease generally is in a very large majority of cases an inherited tendency, one which reveals itself in generation after generation at or about the same age—from 30 to 40. And here the question of the relationship between gout and arterial disease of course arises. There can be no doubt that the link between these two maladies is one of the closest description. Certainly those who are gouty in the sense of a tendency to suffer from acute attacks of the affection are pre-eminently those who are liable to manifest increased arterial tension and eventually vascular degeneration. And I should here like to point out that gout in its most typical and acute form is very far indeed from being an uncommon malady amongst out-patients, so many of whom suffer, as is well known, from arterial disease. In this part of

* The Presidential Address delivered before the North London Medical and Chirurgical Society, Thursday, April 12th, 1906.

London, at all events, I can confidently affirm that most typical gout is an every-day occurrence amongst out-patients, both male and female.

During the many years I saw out-patients I was much struck by this fact, and I have observed the malady in quite young people. A most typical case was that of a boy of 15, and another occurred in the person of a boy of 13. In both these cases there was a strong family history of gout. It is therefore no matter for surprise that high arterial tension and consequent degeneration are constantly met with in out-patient practice. I repeat that I believe hereditary tendency to be at the foundation of morbid elevation of pulse tension.

Yet it cannot be denied that, given this abnormal tendency, various exciting causes may be at work. I feel confident that excessive smoking is one of the most injurious of these causes. I think we scarcely realise the enormous increase which has taken place in the smoking habits of the nation, more especially as regards the most pernicious misuse of the cigarette. It is only necessary to consult the trade returns to ascertain how prodigiously the use of tobacco has increased in this country. The enormous fortunes amassed in the tobacco trade of course point in the same direction.

Now a very simple observation made with the Riva-Rocci sphygmomanometer will convince anyone that even a few whiffs of a cigar will increase the blood pressure. What then must be the effect of arterial pressure when smoking is indulged in from morning to night almost without intermission? Palpitation is very commonly observed among youths and young men at the present time, and is I am sure much more often seen in the out-patient room than formerly. The cause is, I am persuaded, the use of tobacco. Especially injurious to these patients is the habit of cigarette smoking; to such an extent is this vice carried that it is by no means unusual to meet with those who never really cease smoking during waking hours; at all ages such abuse is injurious, but it is particularly so during adolescence, undermining as it does the very foundations of health. During the adolescent period and up to the age of 30 or so, experience has taught me that excess in the use of tobacco causes palpitation, intermission and irregularity of heart action; dyspeptic symptoms occupy but a secondary place. But in middle age it is the digestive system which primarily suffers, a very definite and characteristic form of dyspepsia being induced.

At a later period it is again the heart and the vascular system which feel the evil influence. I am persuaded that a very important factor in the causation of high arterial tension is the abuse—I do not say the use—of tobacco.

Another factor is, I consider, the little use that is made of plain water as a beverage in these days. Stimulants are, of course, taken in excessive quantity; this is a point conceded by all, and I merely mention the fact in passing, but scarcely any attention has been given to the negative omission of water, which is really a necessary of life. It is too often forgotten that pure water is one of the best diuretics, and is withal perfectly safe. In other words there is no more effective agent for washing toxins and impurities generally out of the blood than plain water.

It seems impossible to resist the conclusion that neglect of water drinking has a great deal to do with the marked prevalence of high arterial tension at the present day.

Over feeding is certainly a most potent cause of high pulse tension and arterial degeneration. It is by no means sufficiently recognised that after the period of growth and full development is passed the assimilative functions are no longer so vigorous as was formerly the case. After middle age the power of digestion becomes still weaker, smaller quantities of food are required, and it is of great importance to allow sufficient intervals to elapse betweeu meals. A most erroneous impression is abroad, even among educated people, that it is absolutely necessary to support their strength by frequent and rich meals; indeeed valetudinarians are often in the habit of stuffing themselves in the interval between breakfast and lunch and again between the latter meal and dinner. Sometimes they even eat during the night.

It is needless to dwell upon the harm which accrues from the overloading of the digestive system with a mass of material with which it is incompetent to deal, and the poisoning of the system which must result therefrom. In these luxurious and self-indulgent times there can be no shadow of doubt that a large number of cases of high arterial tension and consecutive renal disease are directly attributable to the prevalent gorging and stuffing, apart altogether from indulgence in alcohol.

The latter habit is so prevalent and so baneful that it is unnecessary now to enlarge upon it, but I do not believe that it sets up kidney disease, and I also hold that, as regards the production of undue vascular pressure and degeneration, chronic over-eating is chiefly responsible.

To some persons Nature has benevolently given a digestion which is extremely sensitive to excess; no matter how slight the self-indulgence may be, the least error in diet is at once resented by the stomach and intestine. A heavy and indigestible dinner is, in these subjects, invariably followed by acid dyspepsia, flatulence or diarrhœa. Such individuals often regard themselves as hardly used, for they see others committing dietetic errors of which they themselves are totally incapable, not indeed from desire, but from necessity.

Yet they little know the ultimate price which has to be paid by their apparently more vigorous brethren to whom dietetic indiscretions appear to be perfectly harmless.

The gradual onset of high arterial tension, of atheroma, and finally of chronic nephritis is the penalty paid by the seemingly more fortunate comrade.

For many persons the presence of digestive sensitiveness is a blessing in disguise; I have noticed that it is especially apt to occur in those who, by heredity, are particularly prone to gout, renal disease and high tension.

Such subjects are only too fond of good living, both as regards food, drink and smoking; yet does the chastening influence of the knowledge that indiscretion will bring its speedy punishment keep them, sorely against their will, in a healthy and active condition.

It is very often indeed the case that the small eater, the moderate drinker, and the abstemious subject generally live to an advanced age, while the seemingly far more vigorous, robust, but free living man of the world is cut off by some complication of arterial tension and degeneration long before attaining the age of 60. We are all acquainted with instances of this, and the first thing that strikes us in healthy old age is the soft and elastic condition of the arterial wall, But perhaps we still do not emphasise as we might the lessons which such observations teach us: that over-eating and over-drinking, the former as much if not more than the latter, are the most fertile causes of premature decay, senility and death in early middle age.

Of the influence of worry and anxiety it is less easy to speak positively, but it is not unreasonable to assume that the restless, excitable, high pressure life led by many people at the present day—the day of the telephone and of "tape prices"—has no small power of inducing the morbid arterial condition here considered.

That syphilis can give rise to increase of arterial tension, as part and parcel of the vascular disease of which it is the cause, is universally admitted.

The affinities of high tension and of consequent arterial degeneration are very interesting.

I have already alluded to the fact that the affection is to a very large extent hereditary, and it is here the appropriate place to point out the close alliance existing between glycosuria and diabetes, gout, chronic

degenerative disease of the kidneys and arterial sclerosis. There can be no question that all these maladies are closely allied, and this is proved by the well ascertained fact of the occurrence of these different diseases in several members of the same family. Thus it is no uncommon thing for a father to die of granular kidney, one son may succumb to the same malady, another may sooner or later present the symptoms of diabetes, a third will probably manifest evidence at or about middle age of gout and arterial degeneration, and a fourth may suffer from glycosuria. I say that it is not unusual to meet with family histories of this nature, in which scarcely a single member attains the age of 60, all being cut off by one or other of those maladies which are more or less closely allied to the degenerative diathesis now under discussion. It is not unusually held that gout or the arthritic diathesis is at the root of the evil. Rather would it appear that a hereditary tendency to degenerative changes in the vascular system, showing itself in the earliest stage by rise of arterial pressure, is that which is transmitted, and I should regard gouty symptoms and the uric acid factor generally as being subsidiary manifestations of the hereditary tendency.

I have already observed that it is of paramount importance for this tendency to be discovered and treated at the earliest possible moment. It is quite usual for it to appear during childhood, and it is not sufficiently recognised that quite small children may suffer severely from headache, acid dyspepsia, and other manifestations of a gouty inheritance with marked inclination to high tension of the arterial system. The feeding of such children requires the greatest care, and the strictest precautions should be observed as regards the admission of meat into their dietary. In many cases it should be taken in the smallest possible quantities only. Examination of the urine in such children will often show a tendency to the deposition of urates, with perhaps an excess in the quantity of uric acid passed, and in not a few instances pain and smarting in the course of the urethra will clearly indicate that the urine is concentrated and irritating.

These are the children who, when they grow up, become the victims of arterial degeneration and high tension, of glycosuria and diabetes, of granular kidney and cerebral hæmorrhage.

There can be no question as to the desirability of ascertaining the state of arterial tension in those, whether children or adults, in whom a tendency to vascular degeneration exists. This matter has been exhaustively considered by Dr. Clifford Allbutt in a paper on the "Prevention of Apoplexy." in which he points out the advisability of testing the arterial tension instrumentally from time to time, as age advances, and this in a systematic manner. This is not a refinement or a fad; it is really astonishing how easy it is to overlook an increased radial tension, and under any circumstances it is most desirable to have an actual record of the existing pressure calculated in millimetres.

I repeat that, from time to time, a routine examination by means of the Riva-Rocci or some other reliable instrument, should be made of pulse tension in all cases in which there is a suspicion of the existence of any morbid alteration of the same, whether through heredity or otherwise.

It would then be possible so to arrange the diet and the patient's mode of life generally as to avoid the risk of the morbid process going further, and attaining that arterio-sclerotic condition which it is hopeless to treat with any rational prospect of success.

As age creeps on the capillaries tend to become obliterated, and in this way arises a peripheral resistance, which in no long time induces a hypertrophy of the left ventricle, an endeavour in this way being initiated to restore the balance of the circulation.

It is only necessary to inspect the skin, more especially that of the face, in old people, in order to be convinced of the fact that the capillary circulation becomes thus obsolescent; in them the skin is thin and papery, dry and scaly; it is obviously defectively supplied with blood, being pale and hanging loosely on the subjacent tissues.

The view that arterial tension tends to increase as years advance is, I think, absolutely correct, and this increase of tension may very rapidly supervene. I have seen cases in which the pulse has been of persistently low tension for years, indeed so soft and compressible has the radial artery felt in some instances that a weakly acting, thin walled and possibly fattily degenerate heart has been thought to be present.

Yet in such a case, as the patient approached the age of 70 a rapid change took place; instead of softness and compressibility the pulse displayed the characters of high tension in the arterial system, much force being required to obliterate it. It seems to me that a comparatively sudden change such as this is of considerable clinical significance, for it is clear that a greatly increased strain is somewhat abruptly thrown on the heart, and hence signs of cardiac failure may occasionally ensue in no long time after the inauguration of the high tension.

It is impossible to over-estimate the value of pulse tension records under circumstances such as these, and it is to be hoped that exact observations may be taken respecting this undoubted increase of arterial pressure which attends advancing years.

In rare cases of arterio-sclerosis, auscultation of the head may reveal the presence of a systolic murmur. I have recognised this sound over the mastoid process, the vertex, the occiput, and the temple. In a case seen with Mr. Waggett, a loud systolic murmur was audible through the diagnostic tube placed in the auditory meatus. In practically the whole of the cases in which this physical sign was detectable there was evidence of arterial degeneration, and in most this degeneration was far advanced. In one case in which a loud systolic murmur could be heard over the vertex and occiput, *post mortem* examination revealed extreme degeneration of the aorta and circle of Willis. The inference of course is, that the systolic murmur is due to the passage of the blood over the roughened surface of the arterial wall.

It is not unusual for patients to complain of rushing noises in the head, but I greatly doubt whether these subjective sensations are really the result of the structural alterations of the arteries under consideration. In most cases in which these subjective sensations are complained of no murmurs whatever are audible in the localities named; on the other hand, so far as my experience goes, it is seldom that the patient makes any complaint of *permanent* subjective sensations of rushing noises when the murmur is evident. It is at all events clear that the subject of cephalic auscultation is one worthy of more extended observation and study; this more especially in cases in which arterio-sclerosis is known to be present. The subject is one to which little or no attention has hitherto been devoted, and yet it undoubtedly possesses an interest and importance of its own.

Much obscurity surrounds the cause of what was formerly known as "serous apoplexy." A person apparently in his or her usual health, but who is more or less advanced in years, suddenly becomes unconscious. and, if standing, falls down, perhaps inflicting a serious injury in doing so. There is total inability to rouse the patient, the breathing is stertorous, indeed the attack is absolutely indistinguishable from one of cerebral hæmorrhage. The worst fears may be entertained, and a very unfavourable prognosis may be given. Yet in no long time consciousness is recovered, and in a few days the health may be practically as before the attack. Such is the clinical history of these seizures, and very difficult is their diagnosis and prognosis. The occurrence of hemiplegia is often confidently anticipated, and lo! nothing of the kind is observed. My experience is that these attacks affect only those patients whose arterial tension is high, and very often indeed chronic renal disease with a trace of albumin in the urine is present.

It is most difficult, indeed impossible, to satisfactorily explain the cause of these attacks, but it seems reasonable to connect them to some extent with that condition of the pia-arachnoid so often met with at the *post mortem* examination of those dying of chronic Bright's disease: œdema of the membranes or some wasting of the convolutions. Whether a sudden and transitory increase of this œdema may arise and, by inducing pressure on the convolutions, may originate the unconscious condition, is a question that may be asked, but it is not possible either to affirm or deny the fact of its occurrence.

I know of no means of distinguishing between an attack of "serous apoplexy" and one terminating either fatally or in hemiplegia, except by the result.

Before proceeding to the consideration of actual cases it will be well to refer to a few details relating to pulse tension observations. As I have already mentioned I have always made use of the Riva-Rocci instrument for determining the systolic pressure. Within the limits of health it would seem that this pressure varies between 120 and 135 mm. of mercury. It is not of course possible to say that every case where the tension does not fall within these limits is one presenting an abnormality of blood pressure; as in many other conditions, the fact of idiosyncrasy must be allowed for. And it must never be forgotten that *transitory* variations of the pressure are constantly observed, being conditioned by a great variety of circumstances, such as a full meal, exertion, emotional influences, &c. But when marked changes become more or less permanent, then it may be safely asserted that tension is pathological.

It has been objected as regards the use of the sphygmomanometer in the determination of hypertension that we are already in possession of accurate means of diagnosis; in other words, the high tension pulse, the hypertrophied left ventricle and the accentuated aortic second sound are quite reliable indications of the condition. This is perfectly true, but it is forgotten that in a very large proportion of patients emphysema and obesity render it impossible for us to avail ourselves of the evidence yielded by the physical signs just enumerated.

There are certain conditions which render the use of the sphygmomanometer unsatisfactory and unreliable, indeed which preclude its employment. These are more especially œdema of the tissues at the point of application of the armlet, and coughing on the part of the patient.

In the latter case the reading invariably rises greatly, so as to be of no value, as an indication of actual pressure.

It is scarcely necessary to remark that all observations should be made under precisely similar conditions.

CLINICAL RECORDS.

FRACTURE OF THE FEMUR IN A HŒMOPHILIC.

BY KEITH MONSARRATT, M.B., C.M.EDIN., F.R.C.S.E.

Surgeon, the David Lewis Northern Hospital, Liverpool.

A BOY, æt. 8, was admitted under my care into the David Lewis Northern Hospital, Liverpool, on February 11th, 1904. Shortly before admission he had been knocked down by another boy while playing in the street. Examination showed that he had sustained a fracture of the left femur, about the centre of the shaft, oblique from behind, forwards, and downwards—as shown by the radioscopic screen, and with an inch shortening. Under an anæsthetic the deformity was corrected, and local splints with a "long Liston" were applied to the limb. During the next few days there was much swelling at the fracture site, and the boy complained of pain which kept him awake at night. On the 18th, a week after the accident, the local effusion showed no signs of disappearing, but rather a steady increase; the apparatus was changed, extension tapes were applied, the local splints were retained, and the limb was elevated to a right angle with the body axis and the extension apparatus fixed to a scaffolding over the bed. On February 21st, three days later, it was noted that no local improvement had taken place, and that the temperature had been steadily ascending by evening rises, partly sustained, up to 102° F. on this day. The local swelling was at this time definitely fluid in character, and taken in conjunction with the fever, and the great pain and tenderness of which the boy complained, it was thought probable that we had to do with a secondary inflammatory process. The chart shows that the pulse rate associated itself with the temperature, and on this day, the 21st, was 140 in the morning, 136 in the evening. When counting the pulse in the left wrist a discolouration, which appeared to be a bruise, was noticed over the radial artery, and on further examination other "bruises" were found in different parts of the body.

The next day the mother was interviewed, and we obtained the following history:—The boy had had diphtheria when eight months old, and this was accompanied by hæmorrhage from the nose and mouth. Subsequently it was noticed that he bruised very easily. He had had a tooth extracted shortly before his accident and bled for a week afterwards, in spite of firm plugging. During the last two or three years he had frequently had swelling in one or other knee; he would go to bed quite well, and wake up in the night with pain and swelling in the joint; the last attack occurred one month before admission into hospital. There was no history of a similar affection in any near relative. The mother had had three brothers; one died from "blood-poisoning" following a stab, one died from an unknown cause, the third was alive and quite healthy; the maternal uncles had also been free from any such complaint, nor did the father's family history show any hæmophilic taint.

During the remainder of the boy's stay in the hospital the diagnosis of hæmophilia was fully confirmed; bruises appeared wherever splint pressure was exerted; for example, a Thomas' knee splint which was put on on March 11th caused considerable effusion in the region of the groin when he was allowed to sit up; the appearance of the bruise from the pressure of the nurse's finger in taking the pulse shows in what a pronounced form the affection existed. Lastly, on April 28th, the left knee developed all the signs of a characteristic hæmophilic joint.

Union at the seat of fracture occurred satisfactorily and was not at all delayed; on the contrary, consolidation took place somewhat earlier than usual; four weeks after the accident it was firm, and measurement showed absence of any shortening.

I have thought it worth while to record this case because of the absence in the text-books of reference to the influence of hæmophilia on fractures. The points of importance seem to be:—

1. The local sign, the occurrence of an enormous effusion of blood around the fracture site, and the association of this with other local and constitutional signs, suggesting the inflammatory nature of the effusion.

2. The fact that union took place satisfactorily and early.

The boy is at present under treatment as an out-patient for the recurrence of the effusion into the left knee. The fever which the chart shows must be looked upon as an exaggeration of the "traumatic" fever which the great majority of cases of simple fracture exhibit. The absorption of the effusion was not associated with the presence of any unusual constitutent in the urine.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

BY PAYTON BEALE, F.R.C.S.

CASE OF HERNIA.—Amongst Mr. PEYTON BEALE'S out-patients was a young man æt. about 18, who was complaining of a little swelling about the shape and

size of a small walnut in the right groin. His history was as follows :—When working as porter, and lifting heavy boxes he suddenly felt a sense of discomfort in the right groin. On going to bed that night he found there was a small rounded swelling in that region. He experienced no real pain, but complained of discomfort and a sensation of stretching of the tissues in the groin. He went on with his work, and during the next three days the swelling increased slightly in size until he sought advice at the hospital. On examination the tumour was found to be below Poupart's ligament, in the position of the upper part of the saphenous opening, and obviously internal to the vessels. It felt somewhat like a small elastic ball beneath the skin and superficial fascia ; it could not be reduced, there was no impulse on coughing, and the man suffered no pain when the tumour was handled, but if an attempt were made to pick it up between the fingers and thumb, he complained of a slight dragging pain, which he referred to the right iliac fossa. Mr. Beale remarked that in this region a swelling of this kind, which was dull on percussion, was in all probability one of the following :—(1) a femoral hernia containing omentum ; 2, a sub-peritoneal lipoma ; (3) an ordinary lipoma or fatty tumour in connection with the superficial fascia of that region ; (4) an enlarged lymphatic gland, one of the superficial femoral glands. The absence of pain and abdominal symptoms generally, considering that the tumour was of three or four days' duration, excluded an ordinary femoral hernia, and the definite history of its sudden appearance was, he thought, strongly in favour of its being a sub-peritoneal lipoma. He said there was no doubt that a sudden protrusion of a little lobule of sub-peritoneal fat was one of the commonest, if not the commonest, way in which a hernia commenced ; of course the real exciting cause of any protrusion from the abdomen through an already existing opening, or through an aponeurosis, was increased abdominal pressure due to sudden and violent muscular contraction, *e.g.*, coughing, lifting heavy weights, rowing, etc. As regards predisposing causes, he considered a protrusion of sub-peritoneal fat as one of the most important ; the sub-peritoneal fat either protruded through an existing opening (the internal abdominal ring, the crural ring, the umbilicus, Petit's triangle) or became suddenly pushed into some very small fissure between the fibres of the aponeurosis of the abdominal wall carrying Transversalis fascia before it. The peritoneum was of course attached to the sub-peritoneal fat (perhaps, he said, the term extra-peritoneal fat was a better one) and therefore was dragged through after the fat. The most difficult thing to explain, he considered, was the fact that the little button of extra-peritoneal fat commonly hypertrophied after its protrusion ; he could only presume that this hypertrophy was caused by increased vascularity ; but it was quite usual to find the protrusion of fat gradually getting larger and larger and so projecting outwards and dragging the peritoneum with it, thus forming a hernial sac, into which sooner or later a piece of bowel or omentum would find its way. The best treatment, he said, was to cut down upon the button of fat, ligature it, cut it off, and close the aperture through which it came as far as possible.

OPERATING THEATRES.

TOTTENHAM HOSPITAL.

OPERATION FOR FEMORAL HERNIA, ASSOCIATED WITH VARICOSITY OF THE SAPHENA VEIN.—Mr. H. W. CARSON operated on a man, æt. 42, who had been admitted to the hospital complaining of pain and swelling in the right femoral region. The patient gave three months' history of discomfort and recurrences of definite pain ; a lump had appeared within the last few weeks. The swelling had varied very much in size and disappeared when lying down. On examination the man showed some signs of muscular degeneration, the abdominal walls particularly being relaxed and somewhat protuberant below the umbilicus. Varicose veins were present in both legs below the knees, the thighs being free. In the erect position a swelling the size of a pigeon's egg was present in the region of the saphenous opening, reducible at a touch, with an impulse on coughing ; on the patient lying down the swelling disappeared entirely. When in the recumbent position the hand being placed over the site of the swelling, and the patient told to cough, a grating impulse was felt. A minute examination of the femoral ring showed the presence of some slight thickening which was taken to be the empty sac of a femoral hernia. A vertical incision was made over the saphenous opening, the large varicose saphena vein was readily isolated, and a portion about two inches long removed between ligatures. Lying close to the vein and in front of it was a thin sac, which on being opened proved to be the sac of a hernia. The neck of the sac was transfixed with a ligature which was tied, the ends being left long, the sac being then cut away. The ends of the ligature were next threaded on the herniotomy needle, which was passed up the femoral canal, and brought out through the abdominal wall as high as possible. The femoral canal was then closed by attaching Hey's ligament to Cooper's ligament (the thickened upper portion of the pectineal fascia), by two silkworm gut sutures and the wound closed by continuous silk suture. Mr. Carson said that this case was interesting because of the association of two conditions which were frequently difficult to differentiate : the diagnosis of varicosed saphena vein from femoral hernia was sometimes very puzzling ; both conditions gave rise to a swelling in the femoral region ; in both cases the swelling was readily reducible and gave an impulse on coughing ; in both cases the patient was generally middle-aged and often gave signs of muscular degeneration. The points of difference were these :—In a varicosed saphena vein, varicose veins could always be found elsewhere in the limb, generally below the knee, the thigh being free. This made it necessary, in examining, these cases, not to be conten with an exploration of the femoral region only. With regard to the reducibility, the swelling in varicosed saphena disappeared at a touch and became non-existent at once on the patient lying down. The impulse on coughing was characteristic. The forcing of the blood back from the external iliac vein caused a curious rough grating feeling which was absolutely unmistakable. There was only one hernial condition, he said, which gave rise to an impulse at all similar to this, namely, an omental hernia with a little fluid in the sac. With regard to the operation, Mr. Carson considered that the method adopted of joining Hey's ligament to Cooper's ligament gave the best prospect of closing the femoral canal at its abdominal end. In passing the sutures it was necessary to avoid injuring the femoral vein which lay just to the outer side. In transplanting the neck of the sac it must be remembered, he pointed out, that in men the vas deferens might be injured in the act of piercing the abdominal wall from within outwards. With reference to the result of radical cure in femoral hernia, Mr. Carson said that with few exceptions femoral hernia was an acquired condition, that is to say, it resulted from slackening and yielding of the abdominal wall following upon muscular degeneration. One cannot therefore, he remarked, hope for as good results in these cases as one would expect to get after a radical cure of inguinal hernia, which last, however, should only be done, in his opinion, as a curative measure in cases in which there is no evidence of muscular degeneracy.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JULY 4TH, 1906.

Dr. J. O. AFFLECK, President, in the Chair.

MR. F. M. CAIRD showed (1) a large vesical calculus and prostate removed by operation; (2) a number of preparations illustrating perforated gastric ulcer.

Dr. ALEXANDER BRUCE showed (1) two brains containing large tumours involving the pituitary body without acromegaly having resulted; (2) a brain from a case of chronic chorea; (3) a brain with thickened vertebral arteries involving both spinal accessory nerves; (4) heart from a case of mitral stenosis, with a large spherical vegetation almost totally occluding the mitral orifice; (5) heart with ulcerative endocarditis, showing a large vegetation on the ventricular aspect of the aortic cusp of the mitral valve; (6) microscopic specimens from the same case, showing bacilli from the cerebro-spinal fluid and blood drawn during life, and from the vegetation; (7) photographs of partial ophthalmoplegia.

Dr. H. M. CHURCH showed Gärtner's tonometer, and gave a demonstration of its mode of employment, as well as the results he had obtained from a series of investigations with it under different conditions of health and disease.

Dr. KEPPIE PATERSON read notes of a case of

RUPTURED GASTRIC ULCER

in a boy æt. 12 years. The patient had had no previous illnesses, with the exception of a tendency to laryngeal spasm whenever he took a cold. For twelve days before the onset of his illness he had suffered from indefinite dyspeptic symptoms—epigastric pain coming on at periods varying from a half to two hours after food, but no vomiting. At about 7 p.m. one evening, just after dinner, he was suddenly seized with violent pain in the abdomen and under the left clavicle, and became collapsed. He was pallid, the pulse was slow, the abdomen was tender and resistant, and the liver dulness was normal. The pain was greatly relieved by hot fomentations, and he passed a fairly good night, though disturbed by retching. When seen next morning there was evidence of commencing peritonitis, the abdomen being distended and tender, and the liver dulness abolished. A diagnosis of perforation of one of the abdominal viscera was made and operation was decided on. On opening the abdomen a perforated ulcer about the size of a split pea was found on the anterior wall of the stomach about two inches from the middle of the lesser curvature. This was sutured and the wound closed. The patient was fed by the bowel for three days, by the mouth and bowel for two days more, and by the mouth only from the sixth day. On the third day signs of pneumonic consolidation of the right lung appeared and spread quickly over the whole of that half of the chest. By the seventh day the patient was extremely cyanosed, and on the following morning the pneumonia was found to have invaded the right lung. The boy was critically ill for several days, being unconscious and much distressed by a recurrence of the largyngeal spasm to which he had always been liable. His temperature ultimately fell by lyses and he made a good, though tardy recovery. Oxygen inhalations had been of the greatest benefit. Dr. Paterson gave a short *résumé* of the reported cases of perforatory gastric ulcer in children. He had only been able to find records of 14 in persons under fourteen years; of these, one only had been diagnosed during life. In his patient he had been unable to discover any cause for the ulcer having developed.

MR. F. M. CAIRD read a paper on

TWENTY-FIVE CONSECUTIVE CASES OF OPERATION FOR PERFORATING GASTRIC AND DUODENAL ULCER.

Fifteen of these occurred in females and ten in males. In most cases there was a prior history of dyspepsia, vomiting having occurred in nearly half the patients. A history of hæmatemesis or metæmia was only exceptionally met with—a common experience in series of cases of perforated gastric ulcer. As regards the symptoms of perforation, pain was invariable; in many instances it was referred to the left shoulder as well as to the epigastrium. Vomiting occurred in 18 cases; there were often some of the signs of obstruction—constipation, distension, and absence of the passage of flatus. The liver dulness was almost always absent. On examining the abdomen it was always found to be rigid; tenderness was chiefly marked at the epigastric and suprapubic regions. The respiratory movements were usually diminished or absent. On rectal exploration tenderness and fulness could generally be made out in the pouch of Douglas; no pain attended micturition. After perforation had taken place the symptoms of collapse developed, and the temperature, pulse, and respiration gradually rose. In seven cases in which the blood had been examined there was a leucocytosis varying between 7,000 and 25,000. In operating it might be possible to perform the preliminary steps of opening the abdomen under cocaine, but for the necessary intra-abdominal manipulation a general anæsthetic would be required. On opening the abdomen the anterior aspect of the stomach ought first to be explored, carefully removing masses of lymph, which lay around the orifice of the perforation. If the liver sac was found to be distended with fluid, the ulcer was probably on the posterior wall, and it was necessary to divide the gastro-colic omentum so as to gain access. Having found the ulcer, and temporarily plugged it with gauze, the next step was to make certain that there was not a second perforation. It was seldom advisable to excise the ulcer; a double Lembert suture was amply sufficient to close it, and if, as was sometimes necessary, so large a part of the stomach wall had to be invaginated that the operator dreaded a future stenosis, a gastro-enterostomy should be performed after the ulcer had been sutured. The upper part of the peritoneum should be cleansed either by irrigation or gentle swabbing, and need not be drained. A suprapubic drain, however, ought always to be passed into the pouch of Douglas, and the head of the bed kept raised so as to facilitate gravitation of effused fluid into that neighbourhood. In his series of cases the perforation had taken place in the anterior wall of the stomach in 18 cases, in the posterior wall in 4, and on the anterior aspect of the first part of the duodenum close to the pylorus in 3. The diagnosis of perforation was not always simple, and he had on more than one occasion opened the abdomen without finding anything to account for the symptoms. The prognosis depended largely on the virulence of the bacterial infection of the peritoneum combined with the power of resistence of the patient. Happily the organism was as a rule of low virulence, as the acid gastric secretions inhibited their growth. Staphylococci was commonly found, and sometimes, when the intestine had been damaged, b. coli. In 7 out of 11 occasions on which cultures had been made this organism was found; in the remaining 4 the tubes remained sterile. The prognosis also depended to a large extent on the period at which the operation was performed, and particularly on the pulse rate. The largest recovery rate occurred in patients in whom the pulse remained under 120, while in those in whom it was over 130 the death rate was very high. With regard to after treatment, transfusion should be freely resorted to

when the pulse flagged, and might be repeated several times if need be. Thirst was best quenched by large rectal salines, Vomiting could be checked by washing out the stomach. Among the complications occurring in individual cases pleurisy, empyema, and bronchitis were the most frequent. One patient developed a fatal cerebral abscess as a sequela of empyema. One patient was twice operated on for perforation. On the first occasion a commencing hour glass contraction of the stomach was found; at the second operation a year later the constriction had increased so much as to make it advisable to perform a gastro-enterostomy.

Mr. ALEXANDER MILES read some observations on PERFORATED GASTRIC AND DUODENAL ULCER, BASED ON A PERSONAL EXPERIENCE OF FORTY-SIX CASES OPERATED UPON.

We hope to publish a report of this in our next.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE Provincial Meeting of the Society was held at the Radcliffe Infirmary, Oxford, on June 23rd.

Dr. OSLER was in the Chair during the exhibition of clinical cases and pathological specimens, and Dr. W. COLLIER (Oxford) for the Papers.

Mr. A. P. PARKER (Oxford) exhibited a boy with dislocation of both patellæ outwards.

Mr. H. P. SYMONDS (Oxford) exhibited a girl with a solid tumour of the pelvis, probably enchondroma.

Dr. W. J. TURRELL exhibited a well-marked case of achondroplasia in a girl.

Dr. E. MALLAM exhibited a child with enlarged liver and spleen for diagnosis.

Dr. E. MALLAM exhibited three cases of calf ringworm, and Miss FITZGERALD showed microscopic specimens and cultures from these cases.

Mr. PERNET also exhibited cultures of ringworm from the scalp and nails.

Mr. P. H. ADAMS exhibited a case of lamellar cataract, who also suffered from icthyosis simplex.

Mr. FINCH exhibited a well-marked case of cretinism in a child.

Mr. R. H. A. WHITELOCKE exhibited a girl with double hernia of the ovary, whose sister had suffered from the same trouble and from whom one ovary was removed by operation and reported at a previous meeting of the Society.

Mr. C. P. PARKER exhibited a specimen of congenital malformation of the intestines in a full-time fœtus, In this specimen the stomach was normal, but the duodenum was enormously distended and at the duodeno-jejunal flexure there is complete occlusion of the tube of the gut, and the rest of the intestine lying in a corkscrew manner with a small mesentery.

By permission of Professor JAMES RITCHIE, numerous pathological specimens were exhibited, viz., Cirrhosis of the Liver in a child, æt. 10. Granuloma of the Brain with Nodules in the Lungs. Tuberculoma of the Brain and Tumour of the Choroid Plexas.

By permission of Professor THOMPSON numerous anatomical specimens were exhibited, (1) illustrating the development of the thymus at various ages; (2) the sexual differences of the pelvis in the fœtus at birth; (3) the lobulated condition of the kidney at birth; (4) the appearances of the ovary at birth and subsequently.

Dr. GEORGE CARPENTER read notes of a case of acute osteomyelitis of the spine in an infant. A girl, æt. 1, was admitted into the North-Eastern Hospital for Children. She looked ill, was anæmic and somewhat wasted. In the left loin there was a large smooth rounded and fluctuating swelling, dull on percussion and very tender. The child died six days after admission. *Post mortem*.—The left pleura contained about two pints of purulent fluid. In front and to the left of the first, second, and third lumbar vertebræ there was a quantity of pus, and the cavity communicated with the left pleura. Microscopical examination of the pus showed streptococci and diplococci. No tubercle.

Dr. E. C. WILLIAMS read some notes of a case of congenital heart murmur in an infant, æt. 5 months, during an attack of whooping cough.

Mr. H. P. CROLY read notes of a "Case of Intussusception," in an infant, æt. 9 months, successfully operated upon by Mr. Whitelocke at the Radcliffe Infirmary. The operation took place eight hours after the first symptom, and was of the ileo-cæcal variety.

Dr. BERTRAM ROGERS read notes of a case of "Acute Atrophy of the Liver," in a boy, æt. 4, admitted into the Bristol Children's Hospital. The child's only previous illness was measles. When first seen he was distinctly yellow and was very sick and complained of abdominal pain. He became delirious and in lucid intervals complained of headache, the jaundice was now well marked. He died two days after admission *Post mortem*.—The liver was about the usual size, and no obstruction to the flow of bile.

Dr. A. G. GIBSON read a paper on some observations on

ENLARGED VEINS IN CHILDREN.

He remarked that a large proportion of children brought up to the out-patient department of any hospital suffer from loss of appetite, wasting, and general debility. Physical signs are, as a rule, few. In many of them, however, veins in various situations are more easily seen than in normal children. The commonest situation is on the front of the Chest, but they are found frequently on the back between the shoulder blades, under the chin, and on the temples. The veins are exceedingly small and are flush with the surface of the skin. These venous ramifications are not seen in all thin children, as, for instance, in the wasting that results from a cerebral tumour; hence it is probable that these veins are dilated. That in some there is venous obstruction is shown by the presence of dilated external jugular veins on one or both sides, even in the upright position. On deep inspiration they do not collapse as do jugular veins in other subjects, *e.g.*, a patient breathing deeply under an anæsthetic. Accurate records have been kept of fourteen such cases, showing as the cardinal sign dilated jugulars on one or both sides, which do not collapse on inspiration. Of these, seven were male and seven female; the age varied from four to ten years; a history of tuberculosis in the family was obtained in eight cases; the symptoms were either lassitude or wasting, or referred to the digestive or respiratory systems such as frequent attacks of vomiting and diarrhœa and attacks of bronchitis or some form of chest trouble. The left jugular vein was enlarged in fourteen, the right in twelve, veins on the chest were visible in thirteen cases, on the back in two, under the chin in two, on the temples in seven. Downy hair on the back was found in six cases. The retraction murmur of Eustace Smith in ten. Small glands in the neck or elsewhere were present in nine cases. Tuberculous peritonitis was present in two cases, while in a third the signs suggested a similar condition. Only in one case has it been possible to observe the anatomical condition under which the dilatation of the veins is produced. This was in a case of tuberculous peritonitis in which a dilated left jugular vein had been noticed for some time previous to death. A dissection of the anterior mediastinum shows a ring of small fleshy glands surrounding the left innominate vein. Sections made from one of the glands show a few giant cell systems and tubercle bacilli. The posterior mediastinum in this case shows several hard caseating glands with large numbers of tubercle bacilli. The cases correspond in character to those described by Eustace Smith as being due to tuberculosis of the mediastinal lymph glands, and without implying that dilated jugular veins which do not collapse on inspiration are pathognomonic of such condition, it is suggested that in the presence of a tuberculous history symptoms of debility, small glands in the neck, veins on the chest, back, neck, or temples, a retraction

murmur; and in the absence of signs pointing to syphilis, lymph adenoma or lymph sarcoma, the sign may be of value in the diagnosis of early tuberculosis.

FRANCE.

Paris, July 8th, 1906.

CHRONIC URETHRITIS OR GLEET.

THE persistence of a few drops of pus escaping from the meatus in the morning is a constant relic of gonorrhœa. This gleet constitutes a symptom of the decline of the malady, not of its cure. Urethritis that has become chronic, says Dr. Pillet, is one of the most tenacious affections of the urinary apparatus. Hence the importance of an early and methodic treatment. The anterior portion of the urethra is always affected, not so the posterior portion. By its integrity or contamination can be judged the curability of the gleet. In order to be clear on the question it is necessary to ask the patient if he has had in the course of one or more attacks of blenorrhagia, orchitis, or cystitis, proofs of posterior infection. The different portions of the canal, perineal, scrotal, and penine should be pressed strongly from behind forwards in the endeavour to squeeze a drop from the meatus. This operation will rarely succeed, however, as the patient has generally urinated beforehand, thus washing out the canal. No other exploration should be attempted at this examination; the passage of a bougie or catheter is dangerous, as it might carry the infection to the posterior portion, up to that time healthy. Two microscopic plates will be given to the patient to receive a drop of the gleet and he will be invited to return next morning without having previously urinated.

Immediately the practitioner will endeavour to find out if the anterior portion alone of the urethra or the two are infected. For this examination there are two methods:—

First, that of two glasses, according as the first only or both contain deposits. The second method is more exact: the glands having been washed with a solution of oxy-cyanide (1–100), the urethra washed and the bladder filled with a solution of ½-1,000. The first day the first jet of urine is collected after massage on a bougie of the anterior portion of the urethra. The second day, the second jet is collected after massage of the posterior portion and the prostate. The microscope will terminate the examination. If the second glass presents white filaments floating through an otherwise limpid urine, the posterior portion of the canal is certainly infected, but the microscope alone will give a correct diagnosis and indicate the proper treatment.

This treatment consists in large irrigations of the urethra with a solution of permanganate of potash, or, better, oxycianide at ½-1,000 and instillations of a solution of nitrate of silver (1-100) into the posterior portion of the canal by means of the special instruments used for this purpose—a catheter with enlarged extremity and a syringe. Care should be taken not to penetrate into the bladder or to use force in injecting the solution.

The instillations should be practised two or three times a week and the patient should be informed that the first injections far from diminishing the gleet, provoke on the contrary some secretion.

The gonococci persist sometimes, in spite of the most active treatment.

Every fifteen days irrigation of the urethra will be made with the oxycyanide solution, while a drachm of the following solution will be injected into the canal twice a day.

Oxygen water	1 drachm;
Distilled water	3 ounces.

The injection will be kept in from one to three hours by surrounding the glands with cotton-wool tightened by a ligature.

Dr. Pillet says he has seen gleet get well by this method (somewhat painful) that had resisted every other means.

Marriage may be permitted in spite of the persistence of a few filaments, if gonococci are no longer found.

In women it is impossible to affirm the disappearance of the bacilli. Coitus should be preceded by an injection of corrosive sublimate in the female and miction in the male.

THIOSINAMINE.

Thiosinamine has been much recommended for the treatment of cicatrix produced by burns by water or caustics. It is used hypodermically, either beneath the skin of the back or into the muscles of the gluteal region. But it is more effectual when injected into the veins. Its field of action however is not limited to superficial cicatrix; it seems to act with advantage on parametric and pleuritic adherences.

A very successful case is reported in one of the medical journals. A man had a stricture of the œsophagus from swallowing a secretion of caustic soda. For some time a sound was passed, but finally it had to be abandoned and liquids would no longer pass. A gastric fistula was made, by which the patient was fed, but he continued, nevertheless, to waste away. At this point injections of thiosinamine were tried. Half a syringe of the following solution was injected into the forearm and repeated every five days.:—

Thiosinamine	½ drachm.
Glycerine	2 drachms.
Distilled water	3½ drachms.

After the third injection a small sound passed with great facility, and the patient was able to swallow liquids. A fortnight subsequently a much larger sound passed, and at the end of a month the patient took solid food.

GERMANY.

Berlin, July 8th, 1906.

AT the Freie Vereinigung der Chirurgen, Hr. Cohn spoke on

X-RAYS IN MALIGNANT DISEASE.

He had treated a number of malignant tumours with the Röntgen rays; the most suitable for the treatment were lymphomata and lymphosarcomata. Of five cases treated in this way, three recovered, one of them fifteen months ago. In some of the cases the tumour was removed and examined microscopically, and the diagnosis thereby confirmed, but recurrence took place rapidly and it was these recurrences that were treated with the rays. A recurrence of a sarcoma of the parotid had disappeared after fourteen days of the treatment. Success in carcinomata was by no means so certain, but even in these cases success was obtained here and there in ulcerated and sloughing cancer of the breast, where cicatrisation was successfully brought about.

Hr. Hermes described four cases of

ILEUS FROM GALL STONES.

Only two of the cases had had colic previously, the other two had never been ill before. In one there was already a deep ulceration of the abdominal wall above the calculus. Death took place in this case, a proof that operation was too long delayed.

Lumbar anæsthesia was successfully carried out in these operations and proved very successful. Of course, the danger of general narcosis was avoided; there was also another advantage in the setting up of active contraction of the intestines.

Hr. Neumann had operated on three cases in the last three years. He considered it more correct to make a transverse incision into the bowel than a longitudinal one. In one case he found a congested intestine with glistening serosa in the region of the groin, but concluded that the part would recover itself. Some days later a fresh ileus broke out, the cause of which was attachment of the congested part and not of the line of incision, which had caused a kink. Recovery took place.

Hr. Sonnenburg spoke on the

VALUE OF COUNTING THE LEUCOCYTES.

He was of opinion that although at present but little reliance could be placed on such counting, it ought to be systematically carried out in the hope and expectation that from a large accumulation of facts valuable conclusions might be drawn at some future date. He showed a large series of curves from which, however, no conclusion of value either as regards prognosis or diagnosis could at present be drawn. Most of the curves were taken from cases of appendicitis.

Hr. Karewski was of opinion that such counting might under certain circumstances be actually misleading.

Hr. Martens believed that an increasing number of leucocytes pointed to a hidden abscess.

Hr. Sonnenburg, in reply, observed that the symptoms as a whole, must be considered, the number of leucocytes included, but that one symptom alone must not be relied on, any more than any other single one.

Dr. Fr. Kirchberg gives a report in the *Aerzt-Sachverst-Zeitung* on twenty-four cases of

ATTEMPTED SUICIDE WITH LYSOL.

observed in the *2nd Medical Klinik* of the Charite Hospital during the last two years. All the other attempted suicides by poison during the same period, have been 22, of which 10 were by sublimate with a fatal result in four cases. Lysol has only lately been put on the Poison Schedule, so that up to quite recently it was readily procurable.

Out of the 24 attempted suicides, only 2 were successful. In other tables the mortality has reached as high as 50 per cent. One reason for these favourable hospital statistics is that where the poison proves fatal it does so with such rapidity that the patients are dead before they can be sent to a hospital, whilst a large proportion of those who live long enough to reach it survive. The symptoms of lysol poisoning are: loss of consciousness, which may come on in a few minutes, or may be delayed for hours, vomiting (rare), smallness, irregularjty, and acceleration of pulse, interference with respiration, which is superficial and slow, or may be accelerated and irregular, almost constant cauterisation of the mouth, chin, neck, throat and œsophagus. Burning in the throat, difficulty of swallowing, hoarseness, but much pain is rare. Black to olive green colourations of the urine with phenol ferric-chloride reaction.

The diagnosis is easy from the expired breath, and the brown cauterization of the external parts.

The prognosis when the first great danger from collapse and somnolence is over is moderately favourable It is difficult to name a fatal dose, so much depends on the organisation of the individual; it also matters much whether the poison is taken on a full or an empty stomach. This explains why it happened that whilst some escaped with life after taking 100 ccm. of pure lysol, others with an empty stomach succumbed to much smaller quantities.

The treatment consists in emptying the stomach as quickly as possible with the stomach pump and washing it out thoroughly. The washing out must be continued until the returned water is no longer milky, and has lost all its lysol odour. If a long time has elapsed since the attempt and the stomach was empty, magnesia usta should be given for the formation of insoluble compounds. Camphor should be given for the cardiac weakness. The after treatment consists in the administration of fluid mucilaginous diet, and in watching the cardiac function.

It was interesting to note that the voluntary suicides were almost all young women who had attempted self-murder frequently from the most trivial causes, apparently. The writer proposes from a practical point of view that a commission be appointed consisting of medical men and pharmacists who shall have the power to put newly invented poisons on the list at once, as they come out, and without waiting for them to kill a number of people before their unrestricted sale is prohibited.

AUSTRIA.

Vienna, July 8th, 1906

GANGRENE OF THE SKIN.

NOBL showed the members of the Gesellschaft a patient, æt. 20, who about the end of May last year came to hospital complaining of a burning red vesicular rash on the left side of the thorax. The vesicles ranged from the size of beans to a fine miliary with red areola at the base. Twenty-four hours after the contents of the vesicles changed to a gluey consistence leaving a fibrinous scale which soon assumed a gangrenous appearance. Hysterical symptoms accompanied the eruption, such as hemi-anæsthesia on right side of thorax and face; a slight pressure on the mammæ gave great pain. A few days later the eruption reappeared on the opposite side extending down the arm and accentuated in the arm-pit, which became confluent, this time leaving behind a glossy, moist, necrotic centre.

On June 7th she was transferred to the Stephanie hospital, where a new outbreak of the rash appeared. Fourteen days later she was dismissed with deep scars on the body where the vesicles had been.

Three weeks later she returned with the rash more widely diffused over the left side and right leg. She was subsequently kept under close supervision with no better results; the rash still repeats itself, leaving large confluent gangrenous patches on arms, breast and shoulders.

There is nothing in her history worthy of note except an accident which occurred to her while cleaning a garment, when a needle ran into the palm of her right hand, and was removed in fragments. This accident occurred three years before the first appearance of the rash, and can hardly be connected with the eruption. Speigler and Weinlechner thought the origin of the rash was artificial in nature.

Nobl assured the members that every possible care was taken to eliminate this factor, and thought with Kreibichs that the morbid origin was an angio-neurotic inflammation.

SCLEROTIC PENIS.

. Ehrman exhibited a preparation taken from a sclerotic penis in which the spirochæte was distinctly present lying in the sheath of the nerve and nerve substance itself This is another confirmation of his theory that all syphilitic changes in the tissue are associated with the spirochæta. He has always found them present in neoplasms of the muscles and nerves, and more recently in all infiltrations due to the syphilitic virus. He has met with them in the Pacinian bodies as well as the fine capillaries. Hitherto the presumption has been accepted that the spirochæte existed in such cases in the fibrous and cellular tissue, but when it disappeared thence no syphilis was assumed to be present. Closer examination of the subject teaches us to assume that the virus has penetrated deeper to the muscles and nerve-structures as presented to us in these sclerotic infiltrations. What the destiny of the spirochæte is after it reaches the nerve structure we cannot say, but patience will no doubt solve the riddle. Here we have it persisting in the Nervus pudendus, and may find it later passing hither to some of the other large trunks. This may lead to a better explanation of many of the sequelæ of the syphilitic, virus, such as tabes which usually commences in the lower part of the cord agreeing with the ascending nature of the spirochæte from the pudendic nerve to the spinal column, where we may hope to find the microbe at a later period of the patient's history.

CONTINENTAL HEALTH RESORTS.

[FROM OUR OWN CORRESPONDENT.]

I.—AACHEN (AIX-LA-CHAPELLE).

BOTH names of this ancient spa evidently evolved from its mineral waters; the German Aachen coming from the Celtic *Ahha*, and the French Aix-la-Chapelle from the Latin *Aquæ*, joined with a recognition of Charlemagne's Cathedral, the site for which was

doubtless chosen here because of benefits the Grand Old Monarch obtained from its hot springs.

Few traces of Celtic days exist; and the remains of Roman baths are not remarkable. The place apparently owes most of its ancient renown to the Carlovingians, Pepin occasionally residing here, and Charlemagne making it the Capital of his Empire. He was crowned at Aix-la-Chapelle, as was his son Louis; and in later years thirty-two other German Kings had their coronations in the church of Charlemagne, to which he had given relics highly venerated during the Middle Ages.

Situated near the frontiers of Germany, Belgium, and Holland, Aix-la-Chapelle is very accessible from many countries. From London, the transit is not more than eleven hours (by various routes); from Paris, eight hours only. It lies in a valley surrounded by high hills, mostly well wooded, and is thus thoroughly protected from unfavourable winds. Three picturesque heights, Lonsberg, Wingartsberg, and Salvatorberg, are located in the valley of the town, and close to the city limits are forests, rich in foliage, and having elevations commanding superb views.

The mineral springs issue from two strata of Devonian limestone, and are found in parallel courses running from south-west to north-east; the outflow reaching the great quantity of over 1,100,000 gallons (minimum) every twenty-four hours. Their temperatures range from 38° to 77° C.; one of them is the hottest of European Springs, exceeding in temperature the "Sprudel" of Carlsbad.

Although these Springs are divided into two groups at the surface of the ground, they are manifestly flowing from a common origin below the surface; for whatever lowers the level of either group, also similarly lowers the level of the parallel group.

In the *Superior Group*, the most famous Spring is the Kaiser, supplying the "Kaiserbad" (of ancient renown), the "Queen of Hungary Baths," and the "Neubad." Its waters are also conveyed to the Fontaine Elise, opposite the popular Nuellens' Hotel. The Kaiserbad itself is in the basement of "The Kaiserbad Hotel," and has a temperature there of 55° C.

The baths of the Quirinus Hotel obtain their supply from three other sources of the "Superior Group."

In the *Inferior Group*, the Rose Spring supplies the "Rosenbad," and the "Comphausbad," and partly also the fine "Corneliusbad," which likewise has a separate source of supply from the Cornelius Spring.

In the Burtsheid suburb is another group of twenty-eight springs, amongst them being the Muhlen, Schwert, Fontaine, St. Michel, St. Jean, Rosen, and St. Charles.

The analyses of the Kaiser Spring Water show (in 10 litres):—

Iodide of sodium	0.005
Bromide of sodium	0.031
Sulphuret of sodium	0.111
Chloride of sodium	26.394
Chloride of lithium	0.033
Sulphate of soda	1.527
Sulphate of strontium	0.0025
Bicarbonate of soda	9.186
Bicarbonate of magnesia	0.771
Bicarbonate of lime	2.274
Bicarbonate of Protoxide of Iron	0.131
Silicic acid	0.661
Organic matter	0.084

In 10 litres of Kaiser Spring Water are absorbed:—

Nitrogen	127.8 ccm.
Carbonic acid	1269.4 ccm.

Carburetted hydrogen-gas—

Methan	5.2 ccm.
Oxygen	17.6 ccm.

100 volumes of the gases rising from the Kaiser Spring consist of:—

Nitrogen	66.98 per cent.
Carbonic acid	30.89 ,,

Carburetted hydrogen gas—

Methan	1.82 per cent.
Sulphuretted hydrogen gas	0.31 ,,

The Aix-la-Chapelle treatment combines usually drinking of the waters with the use of baths; as the plain bath, the douche, and the vapour baths. These baths are placed on the ground through which the hot spring water runs; consequently, however prolonged the bath-treatment may be, no part of the bath-room can possibly become cool.

The douche treatment here is especially effective, and superior to any other on the Continent. Jets of water of even temperature, and of 5mm. to 9mm. in diameter, (at the precise degree of heat and of the exact force as prescribed in each individual case by the physician), are applied to the back, the limbs, or the other specified parts of the patient, accompanied with systematic rubbing, and gentle massage. *This is done in the bath itself, and not as customary elsewhere in a separate room.*

At Aix-la-Chapelle, the Doucheur, or the Doucheuse, descends with the patient into the empty bath, and supplements by kneading and massage the action of the douche, *while the bath is filling with water.* The patient, therefore, need not leave the douche-room to get his bath, and remains longer in the bath after the douche to assist and prolong its effects. The irritation of the skin, produced by the hot-waters and massages, continues to develop itself, as is shown by the redness of the skin and efficacious perspiration. All the Douchers and Doucheuses must have passed Government examinations, and under their skilled treatment the Aix-la-Chapelle douche is a very efficient and quite an agreeable application. It has a remarkably alterative effect, causing the absorption of traumatic and gouty exudations; its influence is notable in the decreased weight of the patient in the early stages of the "Cure," and the increased excretion of uric acid. urea, chlorides, phosphoric acid, &c. The elimination (in the joints, tissues, and skin) of uric acid is particularly manifest.

In a subsequent article will be mentioned the diseases for which the Aix-la-Chapelle "cure" is specially indicated.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

HEALTH OF EDINBURGH. SIR HENRY LITTLEJOHN'S ANNUAL REPORT.—The birth-rate for the year 1905 was 22.99 per thousand, the lowest yet recorded. It has fallen almost steadily since 1879, sinking below the mean rate of 28.8 in 1890. Edinburgh compares very unfavourably with the large towns in England and Scotland as regards birth-rate, and is indeed only surpassed in this respect by Bradford, with 21 per 1,000. Of the total births, 7.5 were illegitimate. The death-rate for the year was 16.25, or, excluding those among persons from the country who were merely temporary residents or had come to the city for treatment in one of its medical institutions, 14.23 per 1,000. This is the lowest figure yet attained, and as the death-rates of the last five quinquennia show 18.23, 18.26, 18.17, 17.48, and 15.6, is not accidental, but in consonance with a continuous reduction which has taken place during the last twenty years. The highest mortality (20 per 1,000) occurred during the last week of January; the lowest (10.3) during the last week of September. The zymotic death-rate was below the average for the previous five years—.99, as against 1.22. Only two cases of small-pox occurred, with no deaths, and only one case of typhus. Measles accounted for 103 deaths, or .3 per 1,000. Scarlet fever is apparently much less virulent in type than during some years past, the mortality having diminished to a much greater degree than the number of cases notified. Enteric fever accounted for 20 deaths, or .05 per 1,000. Only 9 deaths were ascribed to puerperal sepsis, as opposed to 11 in the preceding year. A special feature of this year's report is the prominence given to the work of the City Hospital. It is of interest to note, from Dr. Ker's memorandum, that of the 230 nurses and servants

attached to the hospital and exposed to infection, only 11, or 6 per cent., contracted disease, and all made good recoveries. As regards the admissions for diphtheria, attention is drawn to the fact that many cases are sent in on a bacteriological diagnosis, which ten years ago would not have been considered to have diphtheria at all. Sir Henry doubts whether the discovery of the bacillus always justifies a diagnosis; on the other hand, it is obvious that the isolation of such cases is for the public good. Of cases of true diphtheria, 8.4 per cent. developed post diphtheritic paralysis—a smaller proportion than usual, but as against this the cases of membranous croup, or laryngeal diphtheria appear to have been of a much more severe type than in previous years. More than half required operation, intubation being the method of election. Surgical interference, however, is best postponed as long as possible to give the patient any chance with antitoxin. The percentage mortality of all operations was 35 per cent.; of intubation 33 per cent.; and of tracheotomy, 40 per cent. The importance of early injection of antitoxin is brought out by the fact that of 20 cases treated on the first day none died; of 141 treated within forty-eight hours, 4.23 per cent. died; of 238 cases, infected in the second forty-eight hours, 8.42 per cent. died, while of 109 cases infected on or after the fifth day, 15.927 died. The enteric death-rate was very low—6.8 per cent.—probably because so large a proportion of the patients were children. Under the head of scarlet fever, reference is made to the fact that an unusually large number of cases which appeared typically septic on admission, was not ultimately classed as such. This was due to the very rapid improvement which was manifested within a few days of admission—improvement which is ascribed to the large cubic space per bed and the extremely ample ventilation of the new hospital. Considerable success has also been attained by treating these cases in the open air, on balconies. As usual, the report is replete with graphic tables and charts emphasising the points in the text; it is full of interesting statistical material.

WOMEN GRADUATES AND THE FRANCHISE.—Lord Salvesen has given his decision in this case in favour of the Universities and against the claims of the women. Judgment was based on the broad,and, as it seems to us, unassailable ground, that a constitutional question, such as is involved in the enfranchisement of women, could not be decided by the interpretation of what is more or less a side issue in an Act of Parliament.

GLASGOW.

CASES OF CEREBRO-SPINAL MENINGITIS continue to crop up in various parts of Glasgow, although the most of them are from the East End of the City. There have, up to the present time, been over sixty cases, and the death-rate has been appalling, inasmuch as no case that has been removed to hospital has recovered. The majority of the patients are under ten years of age, and quite a number even below the age of one year. Most of the deaths have taken place within one week of onset. The premonitory symptoms of this disease are often vague; the child is out-of-sorts, and cannot tell what is the matter. The mother may blame its stomach, as vomiting may be an early symptom. Then in a few daysthe nervous storm may burst, and the child be seized with convulsions, terminating in coma and death. The retraction of the head is a marked feature of the disease, the child presenting the appearance of one bridging in "catch-as-catch-can" form of wrestling. After death, a purulent exudate is generally found in the membranes of the brain and spinal cord, and this inflammation is directly associated with the presence of the diplococcus of Weichselbaum.

STAFF CHANGES AT THE ROYAL INFIRMARY.—There have been a good many changes in the staff of the Royal Infirmary. Several physicians and surgeons have retired on the age limit, and the younger men promoted. Lately, however, the ordinary precedent was set aside, viz., that of elevating the junior men on the staff to higher positions. Dr. John M. Cowan, who has been working in the Western Infirmary, has been selected as physician to the wards, vacated by Dr. Allen. Dr. Robert Ramsey has been appointed a dispensary surgeon.

POST OFFICE MEDICAL OFFICERSHIP, GLASGOW.—This office, rendered vacant by the death of Dr. Dongan, is about to be dealt with by the authorities on a new system. It is proposed to divide the area into districts and to appoint a local practitioner, paid by a capitation grant, to each. Heretofore the arrangement has been to have one medical officer only, who devoted his whole time to the work. Very properly, those selected will be required to give an undertaking to attend personally to all post office patients.

BELFAST.

PUBLIC HEALTH.—At the monthly meeting of the Corporation held last week the question of the salary to be offered to the new medical officer of health was again discussed, and after much talk it was fixed at £600 a year. It is quite understood that this figure is intended to suit a local candidate and keep trained men out of the field, but there is some hope that the Local Government Board may refuse to sanction a job such as is contemplated, or rather, fully arranged. During the last month there were 140 cases of zymotic disease notified, including 58 cases of scarlatina and 51 of typhoid and "simple continued" fever. There were 75 deaths from zymotic diseases, of which 52 were from whooping cough. The annual death-rate from all causes was 20.8. The Public Health Committee have issued special notices warning the public of the danger incurred in the consumption of shell-fish. Samples examined by Prof. Symmers at Queen's College were found to be contaminated with sewage matter. About £30,000 has now been spent in experiments with bacteria beds for the purification of sewage, but there does not seem to be much certainty as to results, for the Corporation have just sanctioned a deputation of three of their number and the City Surveyor to cross the Channel and see how the system is working in other places. Probably, however, the advent of warm weather and the holiday season has a good deal to say to this zeal in the pursuit of knowledge.

PORTADOWN AND BANBRIDGE WATER SUPPLY.—A very satisfactory piece of work was brought to a successful conclusion last week, when a supply of water from the Shimna river in the Mourne Mountains, was turned on to the towns of Portadown and Banbridge. The work has been some ten years in preparation and completion, and cost about £70,000. When first contemplated for the former town it was found to be too costly for them, but very wisely the authorities there procured the co-operation of Banbridge, with the result that both places have now an ample and excellent supply, which will no doubt be of great benefit to the health of the towns.

THE PHARMACY ACTS.—Several prosecutions under the Pharmacy Acts came on at the Londonderry Petty Sessions last week, promoted by the Pharmaceutical Society of Ireland. Two were for selling a medical prescription, the defendant not being registered as a pharmaceutical chemist, and two were for keeping open shop for the selling or retailing of medical prescriptions. The magistrates convicted, but imposed fines in two cases only, amounting to £10 and £2 costs.

BELFAST FEVER HOSPITAL.—The resident medical officers for the new fever hospital, which will probably be opened in September, were appointed last week. Mr. W. J. Leighton, M.B., was appointed senior officer at £150 a year, and Mr. E. H. M. Milligan, M.B., junior officer at £125. Both gentlemen were students of the Belfast Medical School.

MEDICAL GOLF MATCH.—The competition for the Lindsay Challenge Cup, presented by Prof. Lindsay fo competition among medical men in and around Belfast, was held this year at the Fortwilliam Park Links. The preliminary stroke competition resulted in the following eight qualifying for the match competition:—Drs. Bailey, Dempsey, Gaussen, Houston,

Kevin, MacIlwaine, H. Monypeny, and Robb. In the final round, played on the 5th inst., Dr. Thos. Houston defeated Dr. Gardner Robb by 6 up and 5 to play, thus becoming the holder of the cup for this year.

LETTERS TO THE EDITOR.

THE "CHRISTIAN SCIENCE" TRIAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The trial of Dr. Adcock at the Old Bailey, as you truly say, "has come to an eminently unsatisfactory conclusion," and although I am of course prohibited from commenting on this particular trial *sub judice*, I apprehend I am in order in calling attention to what appears to me an anomalous and contradictory state of the law in so frequently re-trying cases, notably, of late, some of homicide. Indeed, if I remember, there was one notorious case occurring a few years back in which the Crown abandoned any further prosecution, the jury having failed to arrive at a verdict on the second trial.

In order to make my point clear, I may be allowed to refer to an article entitled, "What Constitutes Insanity," and which you paid me the honour to insert in your journal of December 5th, 1894. In that, I attempted to differentiate in a logical or theoretical sense between sanity and insanity, selecting sound judgment or the capacity to arrive at truth as the highest standard of sanity, and any deviation therefrom as tending towards insanity. The question, therefore, resolved itself into one as to how to determine truth, and obviously as truth can only be arrived at, and not always even then, by the majority of opinion, I illustrated a trial by jury, pointing out the one dissentient juryman in any given trial would almost assuredly turn out to be a man of defective judgment. I refer to this article, because it shows the necessity for a new trial in the case where *one* obtuse juryman prevents the administration of justice, *i.e.*, a verdict.

Suppose, however, that as many as three or four jurymen dissent, the case would be entirely different; there would be something approaching a more reasonable division of opinion, and this, I think, constitutes "reasonable doubt," the benefit of which the law professes to give a prisoner. To be consistent, therefore, the law should acquit the prisoner on the first trial, unless any fresh evidence be forthcoming, because although a second jury may, haphazard or otherwise, arrive at a verdict, nevertheless, the same grounds for doubt must necessarily exist or should exist in the second as the first trial—unless, as I say, fresh evidence is produced.

Another point occurs to me with regard to "Christian Science," Generally speaking, much as I dislike so called "Christian Science," which I think could be more appropriately termed "infidel science," I cannot for the life of me understand by what legal process a qualified practitioner, under protection of his qualification, can be prevented from adopting the tenets of "Christian Science," if foolish enough to think fit, because his counsel might plead that there was no enactment to compel a doctor to administer medicine if he thought undesirable, or to prevent him from praying, if he deemed it more efficacious.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, July 7th, 1906.

THE BACTERIOLOGY OF THE VARTRY WATER.

SIR,—May I ask your help in stirring up public opinion as to the necessity of having a periodical bacteriological examination of the Dublin water supply. What makes the matter urgently pressing at present is that a new reservoir is about being built, and already a number of men are at work sinking pits, &c. In a few months it is expected that hundreds of workmen will be digging away at the new works, and the danger of the catchment area becoming polluted with enteric, diarrhœa and diphtheria must, in spite of every precaution, be very great. Obviously, the only possible means of detecting the pollution, before it gives rise to an epidemic, is a periodical bacteriological examination.

Unfortunately the Dublin Corporation cannot be got to see the necessity for it.

I am, Sir, yours truly,

J. C. MCWALTER, M.A., M.D, D.Ph.

THE MANUFACTURE OF PURE FOOD PRODUCTS.

SIR,—I should not venture to risk misunderstandin of my motive in writing, but I feel it a duty at this time that all experts in food production should assist by their advice in protecting the public from impurities and adulteration in all consumable articles.

Many years ago I erected in my works in this city a model room for carrying on the operations connected with the manufacture of Fruit Syrups. This room is in daily use, and has answered every purpose for which it was built. It is lofty, and ceiling, walls and floor are of cement, with a very smooth surface, all corners at sides, base or top are concaved, to permit of filtered water being daily poured from hydrant to remove dust or possible germs. The floor is slightly shelved to a centre depression to allow water to run off. The window frames and door are steel and pans of enamelled iron. No wood or porous material is used in manipulation. The Fruit Syrups are automatically filtered, mixed and passed to the Works without the slightest handling. Your representative, or any member of the medical profession, is at liberty to inspect this room at any time.

I am, Sir, yours truly,

The Old Refinery, Bristol. H. W. CARTER.

July 5, 1906.

OBITUARY.

HENRY RICHARDSON, M.D., D.D.

WE regret to note the death, on the 1st instant, of Dr. Henry Richardson, Tygwyn, Oswestry, from terrible injuries received in a cycle accident on Friday week. While cycling down Sweeney Bank, near Oswestry, he was thrown over the handle-bars of his bicycle, and alighted on his head on the road with great force. He was taken to the workhouse infirmary near the spot, and there lay in a semi-conscious state until his death. He was forty-seven years of age, and a native of Prestatyn. He held the degrees of Doctor of Divinity and Doctor of Medicine.

LITERARY NOTES.

WE have received from Messrs. Churchill a copy of the third edition of the Pharmacopœia of the Evelina Hospital for Sick Children. It contains a number of really useful formulæ and diet lists. The price of this very practical book is 1s. 6d.

***

THE "University Series" of Manuals, published by Messrs. Bailliere, Tindall and Cox has been further enriched during the last few days by the addition of a "Manual of Anatomy," by Professor Buchanan, of Glasgow. The author has been so long and so distinguished in the field of anatomy that a book by him promises a successful venture.

***

IN the same series two new editions of standard works have also been issued during the last few days, viz., a fifth edition of Prof. Stewart's classical "Manual of Physiology," and a second edition of Prof. Monro's "Manual of Medicine." As the first edition of the latter work appeared little more than a year ago, the call for a second so quickly would imply that it has met a requirement.

***

WE are glad to welcome a new edition (the fourth) of Sir William Broadbent's work on "Heart Diseases," which has been out of print for some time. In the

production of this the author has been greatly assisted by his son, Dr. John Broadbent. Some new chapters and new illustrations have been added, and the whole work revised and brought up to accord with the most modern teaching.

***

MESSRS. J. AND A. CHURCHILL have just published a work, "Preservatives in Food and Food Examination," by Dr. John C. Thresh, Lecturer on Public Health at the London Hospital Medical College and Dr. Arthur E. Porter, Assistant Medical Officer of Health and Chief Sanitary Inspector, City of Leeds. At a time when so much interest is centring around the disclosures at the slaughter-houses of Chicago, the appearance of an authoritative work bearing on the subject is opportune.

***

IT is not often that a medical journal is able to bestow unqualified approval upon a pamphlet, the object of which is to make known the value of an artificial food for infants. We have, however, nothing but praise for the little essay just issued by Mellin's Food Company entitled "To Combat Infantile Mortality." It would be well if it could be mastered by every intelligent mother who needs guidance in the feeding of her baby. The food is not put forward as a panacea for all the ills that infantile flesh is heir to; and not the smallest claim is advanced for any value beyond what may be scientifically ascribed to a preparation of the kind. The prime importance of food and feeding, the superlative value of mother's milk, and the proper use of substitutes and admixtures are all clearly explained, and no mother or nurse possessing the knowledge conveyed in this pamphlet can go far wrong in the feeding of her charge.

***

"The World's Anatomists" is a reprint of articles which have appeared in an American contemporary with some additions. Besides its references to the more famous of the world's anatomists, it contains several portraits. These notes when they first appeared attracted considerable attention, and in their present and more permanent form they will probably be read by a wider circle. As a contribution to medical history, this brochure must be accorded a high place. The frontispiece gives a reproduction of Rembrandt's masterpiece. A portrait of Mr. Henry Morris appears opposite page 40, while Heath and Holden also figure on the pages of this dainty volume. It is a pleasure, to note that so many of the world's anatomists are Englishmen born and bred. Many will doubtless be glad to possess this record of a department of medical science which is of immense importance in practice. The editor, Dr. Kemper, is to be congratulated in bringing before his readers such a valuable record of names. The publishers are Messrs. P. Blakiston, Son and Co., of Philadelphia.

LABORATORY NOTES,

VIRBOVEC DOUBLE CREAM.

WE have examined a tin of the "double" sterilised cream prepared in Hungary by the Virbovec Export Dairy (London Agent, R. Simpson Shaw, 17, Devonshire Square, E.C.). This double cream is especially adapted for the purpose of "whipping," but it is also a suitable substitute for fresh cream for any other purpose. A very satisfactory feature about the preparation is the freedom from the peculiar flavour which so often seriously militates against the popularity of sterilised cream—in fact, we doubt if it is possible to distinguish it from the fresh article by taste alone. On analysis we found it to be quite free from preservatives, and the tin had been in our possession several weeks; but, of course, when opened, the cream will not remain good longer than other cream in which no preservative is used. The process of sterilisation appears to be very effective, as not only is the preparation free from living micro-organisms, but the consistency and uniformity are retained to a remarkable degree. The value of a preparation possessing such valuable attributes as a means of increasing the fat in a diet is obvious. The sample gave the following figures on analysis:—Moisture, 51.27; fat, 44.89; mineral matter, 0.32; curd and sugar, 3.52. The same Hungarian export dairy put up single cream in the same form, which we found equally pure but less rich in the fat product.

NEW DRUGS.

MESSRS. PARKE, DAVIS AND CO. have sent us some of their newer preparations, and we are glad to draw the attention of our readers to the products of this trustworthy firm. Among these are "Acetozone," a germicide already well known, and Acetozone Inhalent, a solution of 1 per cent. Acetozone and 0.5 per cent. Chlorotone, in liquid paraffin, which is specially useful for treatment of the mucous membranes of the upper air passages. "Thyroidectin" is a powder prepared from the blood of dethyroidised animals, and its administration has been attended with encouraging results in the treatment of Graves' Disease. The same firm are prepared to supply tablets of scopolamine and morphine by means of which anæsthesia can be induced with great ease and without unpleasant after-effects. Their Throat Mentholated Tablet, without cocaine, also, is a promising preparation.

WE have received from Messrs. Burgoyne, Burbidge, and Co. a sample of their emulsion of Cod Liver Oil, with hypophosphites of lime, potash, and soda. The emulsion is beautifully prepared, and in appearance and consistence it resembles a rich cream. It is claimed that this preparation is not followed by nausea and eructations, such as commonly follow the administration of cod liver oil, and that the emulsion retains its characters under all conditions. The makers deserve credit for producing this elegant preparation of a useful but distasteful drug.

"SAJODIN" is one of the Bayer Company's new products. It is reputed to be an efficient substitute for potassium iodide, and at the same time to be incapable of inducing iodism. If these claims be borne out in practice, Sajodin should find an unusually large field of usefulness before it. Neatly made up packets containing 15 grains are supplied.

North-East London Clinical Society.

THE annual general meeting of this society was held at the Tottenham Hospital on Thursday, July 5th, 1906. The following officers were elected for the ensuing year: President, Dr. A. E. Giles; Hon. Treasurer, Mr. H. W. Carson; hon. secretaries, Dr. G. P. Chappel and Mr. C. E. Hutt. The meeting then resolved itself into a garden party, held in the beautiful grounds of the hospital, by kind permission of the Governors. The new wards and operating theatre were open to the inspection of visitors.

Cholera in the Philippines.

THE American War Department has received advices from Manila stating that there were 116 cases of cholera with 99 deaths in Manila for the week ending July 4, and that during the last twenty-four hours there had been in the provinces twelve cases and five deaths, and in Manila 29 cases and 23 deaths.—Reuter.

Milk and Scarlet Fever.

A SUDDEN increase in scarlet fever cases in Tottenham and Edmonton has been inquired into by the county medical officer, who reports that 16 cases were traced to customers of one milk vendor, the milk having come from a London contractor. About 59 per cent. of the whole of the cases investigated in one week were among persons whose milk was supplied by this contractor.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England—Council Election.

The annual meeting of Fellows took place on Thursday last, for the purpose of electing three Fellows on the Council of the College. After the counting of votes, the president (Mr. John Tweedy) declared the result of the poll as follows:—Mr. George Arthur Wright of Manchester, 462 votes, and 46 plumpers; Mr. Henry Morris, of Middlesex Hospital, 386 votes and 21 plumpers; Mr. Francis Richardson Cross, 340 votes and 10 plumpers; Mr. Charters James Symonds, 316 votes and 51 plumpers; and Mr. William Bruce Clarke, 305 votes and 48 plumpers. Mr. Morris and Mr. Cross were therefore re-elected, and Mr. Wright was elected members of the Council; 750 Fellows voted by post, and only nine in person. Messrs. Willmott Evans and Henry J. Price (Malden) acted as scrutineers. In the evening a Fellows' dinner was held in the College, at which about eighty were present. After the toasts of "The King" and "The Royal Family" had been duly honoured, the president proposed the toast of the evening, "The Fellowship of the Royal College of Surgeons of England." This was responded to by Mr. W. D. Spanton, of Hanley, and Sir Edgcumbe Venning, Mr. Clinton Dent, and Mr. G. H. Makins, C.B., were the hon. secretaries of the dinner, and at the close a copy of the recently-prepared "Historical Summary of the History of the College" was presented to each Fellow present.

Apothecaries' Hall of Ireland.

THE Worshipful Company of Apothecaries met last week to confer the honorary degree of L.A.H. on Sir Christopher Nixon and Professor Denis Coffey. The Deputy-Governor (Dr. Stritch) said:—"It is my privilege to present to you an illustrious member of the medical profession, Sir Christopher John Nixon. His path through life has been marked by such singular and well deserved success that, whilst we admire his great intellectual abilities, we must marvel at the strength of purpose which enabled him to surmount ordinary difficulties and reach that pinnacle of fame he now enjoys. He is Senior Physician in the Mater Misericordiæ Hospital, where his cliniques have always been of surpassing success and popularity. Her Majesty, our late beloved and ever-regretted Queen, was pleased to create him a Knight Bachelor, and to-dayall English-speaking people read of the distinction conferred upon him by our gracious Sovereign King Edward VII." Dr. Stritch then said:—"He whom it is now my privilege to present to you is a distinguished scientist of universal reputation, Dr. Denis Joseph Coffey, M.A., M.B., B.Ch. and B.A.O., Fellow of the Royal University of Ireland, Professor and Examiner in Physiology of the Royal University of Ireland, Lecturer on Physiology and Biology, St. Patrick's College, Maynooth (applause). A University which is proverbially jealous of her reputation, which conscientiously labours incessantly to discharge her immense responsibilities to mankind by the adequate instruction of her students—this University has, as already stated, testified her appreciation of Dr. Coffey's attainments by appointing him to the exalted position of one of her Professors." Dr. Montgomery (as the senior member of the Apothecaries' Hall) proposed the following resolution:—"That the Governor and Court of the Apothecaries' Hall of Ireland tender to the Medical Faculty of the Catholic University School of Medicine hearty congratulations on the attainment of their golden jubilee, and they are greatly pleased, in the interests of science and the common weal, to have observed the ever increasing standard of efficiency which has been maintained during the fifty years that have elapsed since the school passed from under the control of this Hall."—Dr. Evans seconded the resolution, which was carried unanimously. The governor then admitted Sir Christopher Nixon and Professor Coffey, who replied.

Guy's Hospital Prize Distribution.

THE annual distribution of prizes at Guy's Hospital Medical School took place on the 4th inst., the chief awards being: Open scholarships in arts—H. L. Hopkins, Owen's School, £100; A. H. Todd, Sherborne School, £50. Open scholarships in science—M. A. E. Duvivier, Guy's, £150; T. D. Macgregor Stout, Guy's, and A. N. Cox, Derby School, equal, £30 each. Scholarship for University students—C. G. Douglas, B.A., Magdalen College, Oxford, £50. Open scholarships in dental mechanics (October, 1905)—E. J. Archer and W. E. Guilding, equal, £10 each; (May, 1906) D. B. Tasker, £20. Junior proficiency prizes—H. B. Kent, £20; C. A. Wood, £15; J. J. Darke, £10. Michael Harris prize for anatomy—H. B. Kent, £10. Wooldridge memorial prize for physiology—J. L. Atkinson, £10. Hilton prize for dissections—H. B. Kent and W. E. Williams, equal, £2 10s. each. Arthur Durham prizes for dissection (first year's students)—R. P. Ballard, £5; (senior students) H. B. Kent, £15. Dental prizes (first year's students)—H. C. Visick, £10. Treasurer's gold medal for clinical medicine—P. P. Laidlow. Treasurer's gold medal for clinical surgery—G. Cockcroft. From the annual report, read by the Dean, it as shown that, notwithstanding the generally diminished entry at the metropolitan schools of medicine, the number of students who had joined Guy's during the past 12 months gave a distinct increase over that of the preceding year. The most pressing need of the school at the present time was a sum of £10,000 for the endowment of a chair in pathology. This subject, which was the key to all advancement in the science and art of medicine, was growing so much in extent and importance that the school had decided that at the earliest opportunity a department of pathology must be instituted, with a separate staff of lecturers and demonstrators. This important step could not be taken without further monetary assistance, but it was hoped that such endowment might be forthcoming, and a department instituted which would enable the subject to be taught in a manner worthy of such a great school of medicine as that of Guy's Hospital.

The Money Value of Patent Medicines.

AN outcry is being raised in the scientific journals of the United States at the growth of the drug habit which is even more apparent there than in England. The *Morning Post* asserts that nearly £20,000,000 a year is spent in the United States on patent medicines, which may roughly be divided into "soothing syrups," "cough syrups," or "pectorals," "catarrh cures," and "headache cures." The "soothing syrups" nearly all contain opium, and are specially vicious when given to children; the "cough syrups" frequently contain the same drug; the "headache powders," which do not contain opium are almost without exception preparations of acetanilid, a substance derived from coal tar, which, although not so dangerous as morphine, produces an insidious weakening of the heart when used repeatedly. The "catarrh cures" contain cocaine; the "pick-me-ups" some form of alcohol. Our contemporary agrees with us that on both sides of the Atlantic it should be made compulsory for all proprietors of patent medicines containing any of these constituents to state on the label the amount of poisonous ingredients present.

Health Congress in Dublin—Consumption in Ireland.

THE annual Congress of the Royal Institute of Public Health opened at Cork on the 27th inst. Delegates assembled at the municipal buildings, where they were received by the High Sheriff, in the unavoidable absence of the Lord Mayor. A procession was formed at the municipal buildings, and the delegates, who comprised forty mayors from different parts of the kingdom, drove in open carriages to Queen's College, where the inaugural meeting was held. The High Sheriff having welcomed the delegates, Professor Smith, president of the Royal Institute, addressed the Congress. He said that consumption was a matter of grave moment in Ireland. In England the mortality from that disease had been gradually diminishing, while in Ireland it was increasing. When they came to Cork they had a far more lamentable fact to face, namely, that of all the cities in Ireland Cork headed the list in its death-rate from phthisis. It was a circumstance of the greatest gravity, not only for the City of Cork, but for the corporation and the citizens. It behoved somebody to look into the matter to see what could be done to reduce the enormous mortality from what they knew was a preventable disease. Professor Smith afterwards invested Prof. Windle with the insignia of office as president of the Congress.

Prof. Windle, in his inaugural address, referred to the excessive death rate from consumption. He said side by side with the advancing mortality from tubercle there was an alarming increase in the number of insane. Of every ten thousand persons in Ireland 52·6 were registered as lunatics or idiots, the figure in England and Wales being 34.71 per ten thousand.

Measles and Phthisis Notification.

THE Public Health Committee of the Edinburgh Town Council at its meeting last week, had before it a motion by Judge Macpherson as to the desirability of notifying the first case of measles occurring in a family. It turned out the Committee were equally divided in their opinion, a motion being made that no notification be made. On a division six voted for Judge Macpherson's proposal and six against. Judge Macpherson who presided in the absence of the convener, gave his casting vote in favour of his proposal, and the committee decided to recommend accordingly. A motion by Councillor Robertson as to whether the time has not now arrived for the compulsory notification of phthisis was sent to a sub-committee for report.

Laudanum in Quantities.

WILLIAM HENRY WHITTY, thirty-eight, tailor's manager, was last week, charged at West London with attempting suicide. The police produced a good-sized bottle three-parts full of laudanum.—Mr. Kennedy (the magistrate): Do you mean to say a chemist sold all this laudanum to you at once?—Defendant: Yes, sir. I had had acute neuralgia, and I took some whisky. Then a friend recommended me to try laudanum, and I bought that bottle. I had no intention of killing myself.—Mr. Kennedy: Didn't the chemist ask you to sign a book?—Defendant: No, sir. I drank some in the shop doorway.—Mr. Kennedy: The police had better make some inquiries at that shop. You can be discharged since it appears you took the laudanum to allay pain.

The Heidelberg Conference on Cancer.

THE International Conference for the prevention of cancer, is announced to meet at Heidelberg at the end of September. On the 26th of that month, the delegates will assemble at Heidelberg, and on the next day will be addressed by the president, Professor von Leyden. In the afternoon a visit will be paid to the new local Cancer Institute. The following day members will adjourn to Frankfurt, where they will inspect the institute for experimental therapeutics, and also the scientific collection. On the 27th, there will be lectures and demonstrations by members of the Berlin cancer division of the first medical infirmary.

St. Mary's Hospital Medical School—South African War Medal.

THE annual distribution of prizes to the successful students will be made by the Director-General of the Army Medical Service on Monday next, July 16th, at 4 p.m. After the presentation of prizes in the Library the Memorial Bronze erected in the entrance hall of the Clarence Wing, to the memory of members of the Hospital and Medical School who lost their lives during the South African War, will be unveiled by the Director-General of the Army Medical Service.

The Annual Medical Tour in Germany.

DR. OLIVEN, Secretary-General of the German Medical Tour, asks us to announce that the tour this year will start on September 2nd, at Heidelberg, finishing on September 15th at Stuttgart. The following watering-places will be visited:—Wildbad, Fernach, Freudenstadt, Rippoldsar, Badenwerber, Tadtmars, St. Blasia, Schaffhausen, Konstang, Triberg and Baden-Baden. The price of the whole tour (wine excluded) is £11 5s. Programme, etc., to be had from Dr. Oliven, Berlin N.W. Linsenplatz, 2–4.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have received the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery and midwifery:—A. J. Ambrose, D. L. E. Bolton, A. W. S. De Vine, R. C. T. Evans and P. Moxey.

PASS LIST.

College of Physicians and Surgeons—Examination Results.

THE following gentlemen passed the recent second examination in anatomy and physiology:—
Edward Bruce Allnutt, St. Bartholomew's Hospital; Manekjee Dhanjishaw Anklesaria, L.M. and S. Bombay; Tom Chamney Russell Archer, St. Thomas's Hospital; John Lee Atkinson, Guy's Hospital; Charles William Tresidder Baldwin, Charing Cross Hospital; Jehangir Cowasjee Balsara, L.M. and S., L.R.C.P., and S. Edinburgh, of Bombay; Ernest Cuthbert Barnett, New Zealand; Donald Maxwell Cox, Charing Cross Hospital; Ernest Edgar Davies, University College, Bristol; Archibald Wallace Duncan, St. Mary's Hospital; Evan Richard Evans, St. Bartholomew's Hospital; Walter Andrew Fernando, Ceylon and King's College; Philip Charles Field, University College, Bristol; Richard Sydney Graham, St. Mary's Hospital; Guy Fleetwood Haycraft, Guy's Hospital; Martin Hallam, Sheffield University; James Frank Hoare, University College Hospital; Maurice Lionel Corrie Irvine, St. Thomas's Hospital:; John Lawrence Johnston, Guy's Hospital; Walter Foulkes Jones, B.A.Cantab., Cambridge University, St. George's and King's College Hospitals; Abdus Sattar Khan, L.M. and S., Calcutta; Latafat Husain Khan, Bombay and St. Bartholomew's Hospital; Henry Goff Kilner, Middlesex Hospital; Framroze Kolaporewalla, Bombay, and Guy's Hospital; Russell Hardy Sidney Marshall, St. Mary's Hospital; Charles Anderson Meaden, St. Bartholomew's Hospital; John Cecil Wilson Methven, London Hospital; James Knowles Milligan, St. Thomas's Hospital; Frank Cyril Morgan, University College, Bristol; Albert Edgar Nicholls, University College, Cardiff; Frederick Cecil Nichols, Bristol; Richard Goodhart Oram, Guy's Hospital; William Robert Parkinson, Otago and St. Thomas's Hospital; Guy Harcourt Peall, Guy's Hospital; Charles Arnold Pemberton, Otago and Middlesex Hospital; Arthur Thomas Pitts, L.D.S., Middlesex Hospital; Quintin Hume Richardson, Guy's Hospital; Archer Ryland, St. Bartholomew's Hospital; Frank Stuart Tamplin, St. George's and King's College Hospitals; Jocelyn Langton Waller, St. Mary's Hospital; Thomas Newlands Watt, Otago; Walter Weir, St. Thomas's Hospital; Charles Whitaker, St. Bartholomew's Hospital; Cyril Underwood Whitney, Westminster Hospital; and Arthur John Ormsby Wigmore, University College, Bristol.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS.

ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

Regeneration and Recurrence of Lymph Glands and Vessels.—Meyer contributes to the June number of the *Johns Hopkins Hospital Bulletin* a most interesting and valuable paper on the above subject. As regards regeneration of lymphatic tissue after destruction or removal, he points out that great difficulty arises in distinguishing inflammatory re-action from actual tissue renewal, and that, furthermore, the existence of lymphadenoid nodules scattered diffusely through the adipose tissue of such regions as the axilla introduces an additional difficulty, and one which is readily surmountable when it is remembered that lymph glands may themselves undergo a fatty metamorphosis. Up to this very conflicting results have been recorded with reference to regeneration of partially excised glands, partly perhaps depending on the age of the animals experimented on and partly on variations in the completeness of subsequent examinations. Meyer's own experiments, which were, however, complicated by suppuration some days after operation, were negative as far as regeneration was concerned, and are in agreement with the results obtained by Heuter. As regards recurrences from fat of excised glands, Meyer's experiments also were negative. Most of his experiments were upon the glands of the popliteal region, and the interval between operation and the subsequent examination varied from 25 to 161 days. In none of them was the slightest evidence in favour of recurrence obtained, and since the only previous experimental evidence in its favour was the result of one operation by Bayer, it may be concluded that recurrence very seldom or never takes place. Eight operations were carried out in the large lymphatic trunks of the lower limb in dogs. The vessels were first injected with pigment, introduced through the pad of the foot, in order to make them visible and then portions of them were excised. After intervals varying from 14 to 91 days the wounds were opened up, and in no single case was the smallest evidence of regeneration found. Instead, the cut ends of the lymph glands were found embedded in scar tissue, and no trace of vessels could be found in the intervening space. A similar result was obtained in one operation on the mesenteric lymphatics.

M.

Paroxysmal Cyanosis with Polycythæmia.—Parkes Weber reports a case (*Edinburgh Medical Journal*, June, 1906, p. 525) of the above described condition, in which congenital cardiac disease was present, as evidenced by the existence of a loud systolic murmur audible all over the pericardium. The red cells numbered over 7,000,000 per c.mm., and the white cells 17,000, while the hæmoglobin reached 130 per cent. as compared with the normal. The attacks of cyanosis were intermittent, and chiefly dependent on mental and physical exertion. No sign of unusual hypertrophy of the heart or of failing compensation was present. They believe the condition to be one of patent interventricular septum, and regard the case as in favour of the view that the cyanosis of morbus coeruleus is due to mixture of venous and arterial blood, inasmuch as no signs of œdema or of enlargement of the liver were present indicative of cardiac inadequacy, despite the fact that the patient was past the age of puberty.

M.

Viscosity of the Blood.—Bence has investigated, with the aid of the apparatus devised by Hirsch and Beck, the viscosity of the blood in cyanotic conditions (*Zeitschrift f. Klin. Med.* Bd. 58, p. 205) and finds it to be increased from 25 to 52 per cent. above the normal. Owing to the increase of viscosity an additional obstruction to the circulation is introduced, and this is sometimes sufficient to give rise to cardiac dilatation. Respiration of oxygen gas can diminish the viscosity and even bring it down to normal. Further investigations, however, proved that the presence of excess of carbon dioxide gas played a part in increasing the viscosity, as well as the diminution of oxygen. In seven cases of kidney disease also the blood was found to be more viscous than normal, and to this Bence attributes the left ventricle hypertrophy of chronic Bright's disease. Alteration in diet [illegible] to have any influence at all on the viscosity. As a direct result of the increased viscosity water must pass from the blood plasma into the corpuscles, which necessarily renders the corpuscles larger and [illegible] increases the thickness of the plasma. Both of these conditions continue to increase the friction as the blood traverses the capillaries.

M.

The Fate of Erythrocytes introduced into the Circulation of Animals.—Levaditi has made investigations (*Travail du laboratoire de M. Metchnikoff a l'institut Pasteur*) upon the fate of red cells introduced (*a*) into animals immunised against them, and (*b*) into animals not so immunised. When one injects from one to two cc.m. of an emulsion of the red cells of a pigeon into a rabbit through the jugular vein it is noticed that the immunised rabbits shortly after the injection suffer severely from dyspnœa and general debility, while non-immunised animals do not show any disturbances. From this observation the author concludes that an important difference exists between anti-microbial and cell immunising substances. The former apparently protect the body against the poisons of broken-up bacilli, while the latter lower the general body resistance to cellular poisons. Levaditi believes that in the case of the immunised animals the erythrocytes are broken up so rapidly as to set free sufficient material to cause coagulation of the blood, and that this coagulation taking place in the pulmonary capillaries leads to asphyxia. In non-immunised animals hæmolysins are only present in small amounts and the circulation is therefore not flooded with coagulation producing substances.

M.

Pathology of Puerperal Eclampsia.—Eliza Dunbar (*Bristol Medico-Chirurgical Journal*, June, 1906) puts forward a "new theory" of puerperal eclampsia. This is to the effect that eclampsia is the result of the collection of semi-solid material in the tissues, due to inactivity of the thyroid gland. In other words, puerperal eclampsia is myxœdema occurring in relation to pregnancy or the puerperium. In support of this theory, Dr. Dunbar adduces an alleged cure of eclampsia by the administration of thyroid extract. She believes in some close relations between the functions of the thyroid gland and of the genital organs, and apparently she thinks that the presence of pregnancy makes an additional demand on the activity of the thyroid, which results in myxœdema. The theory is not new, but is sufficiently bizarre to demand much more argument in its favour than Dr. Dunbar either adduces or appears to think necessary before it merits serious consideration.

R.

Tuberculosis of the Thoracic Duct.—Longcope (*Bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital*, No. 3, June, 1906) reviews the literature of tuberculosis of the thoracic duct, and gives details of 30 cases of generalised tuberculosis which were examined either by himself or by MacCallum, of Johns Hopkins. Of the 30 cases, 19 were typical instances of generalised acute miliary tuberculosis.

Where histories could be obtained, the course of the disease was rapid, lasting from two to twelve weeks. Of these 19 cases in 15 the thoracic duct was affected. Of 8 cases of chronic or subacute tuberculosis, the thoracic duct was affected in only two, while in three cases of a chronic type the thoracic duct was normal. In all cases in which the thoracic duct was extensively affected, the lymph nodes of the mesentery, retro-peritoneum, and posterior mediastinum were the seat of a chronic tuberculosis. This intimate association between the condition of the ducts and that of the lymph nodes leads Longcope to believe that the infection travels directly from the latter to the former by means of the lymphatics. He thinks, further, that the thoracic duct is of great importance as a channel for the spread of tubercle bacilli through the body from the various groups of lymph nodes. He concludes that tuberculosis of the thoracic duct is of great frequency in cases of acute generalised tuberculosis. The lesions in the duct, from which tubercle bacilli are swept in great numbers through the lymph to the general circulation forms the starting point of the generalised acute process. R.

Cerebro-Spinal Meningitis.—Robinson (*Bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital*, June, 1906), publishes an account of the bacteriological findings in fifteen cases of epidemic cerebro-spinal meningitis. His experience is in agreement with received opinion as to the constancy of the occurrence of the diplococcus of Weichselbaum in the spinal fluid. He only met with this organism, however, in the circulating blood in two out of four cases investigated, and he is of opinion that it is only an occasional invader of the blood. Its presence, however, may persist for several days, and is not merely agonal. He had the opportunity of examining two cases of purulent conjunctivitis occurring in the course of the disease, and from the pus of one of these the diplococcus was isolated. His experience is that the broncho-pneumonia, which not infrequently terminates the disease, is due to pyogenic organisms, and not to the diplococcus. R.

The Clinical Examination of the Cerebro-Spinal Fluid.—Purves Stewart (*Edinburgh Medical Journal*, May, 1906) discusses the clinical lessons to be derived from an examination of the cerebro-spinal fluid. (1) *Physical Characters:* Whereas the normal fluid is clear and colourless, in cases of meningitis it may be cloudy or even purulent. In severe jaundice, it may be yellow, but clear, whereas in cerebral or spinal hæmorrhage, it may be blood-stained. This point is of much importance in the diagnosis between hæmorrhage and thrombosis in cases of sudden hemiplegia. (2) *Chemical characters:* Excess of albumin occurs in acute meningitis. In general paralytics Gullain and Paraut have discovered with great constancy a precipitate which persists after the coagulation and removal of the serum-globulin and albumose of ordinary cerebro-spinal fluid. (3) *Bacteriological characters* serve to distinguish the different forms of meningitis due to different causative organisms. The failure to find any organisms in a case of undoubted meningitis is suggestive of tubercle. (4) *Microscopic characters:* The nature of the cells present is of much importance. Whereas the normal fluid contains a few endothelial cells and a few lymphocytes, in all cases of acute meningitis, polymorphonuclear leucocytes are present in considerable numbers. In more chronic affections of the meninges, on the other hand, and also in certain chronic degenerations, such as tabes dorsalis and general paralysis, lymphocytes are present in large numbers. Microscopic examination may also reveal the presence of tumour cells, or of organisms. R.

Sign of Death.—Ott (*Journal de Medicine et de Chirurg. Prat.*, February 26th, 1906) describes a sign of death easy of application. A taper or match is applied to the palmar surface of the forearm, and the part touched by the flame carefully watched. If the subject be dead, the epidermis rises like a bubble and bursts, no exudation being observed. On the other hand, if the subject be alive and any circulation present, a distinct blister is formed. R.

New Methods of Clinical Pathology.—Walker Hall (*Bristol Medico-Chirurgical Journal*, June, 1906) describes certain methods of clinical pathology recently introduced which he thinks likely to be of interest to the physician. (1) *Gastric contents:* Sahli's method for determining the presence of free hydrochloric acid in the stomach is commended. Instead of the so-called "test meal" Sahli allows a full meal, which is followed immediately by the administration of a pill of methylene blue enclosed in a well-made catgut capsule. The latter can only be dissolved by free HCl, and the appearance of blue pigment in the urine determines the presence of HCl in the stomach. (2) *Fæces:* When examining fæces for the eggs of intestinal parasites, the fæces should be made liquid by the addition of 10 per cent. formal solution. Smears should then be made on slides, fixed with 1 per cent. osmic acid vapour for two minutes, and mounted in glycerin. (3) *Urine:* Krokiewicz proposes the following test to demonstrate the presence of bile:—Add equal amounts of a watery solution of sodium nitrite and of sulphanilic acid to a few drops of urine, and then pour in one or two drops of concentrated hydrochloric acid. With normal urine a ruby red colour appears, whereas if bile be present the colour is amethyst violet. To demonstrate aceto-acetic acid in the urine, Riegler's test is recommended:—To 1 cc. of normal urine add 2 cc. of 10 per cent. iodic acid solution, and 3 cc. of chloroform. Shake. The chloroform turns violet. Add 10 cc. of the urine to be examined. If aceto-acetic acid be present, the chloroform will be discoloured. Walker Hall gives many other methods; we have selected those most likely to be of use to physicians. R.

Channels of Infection with Tuberculosis.—Calmette and Guérin (*Annales de l'Institut Pasteur*, May 25, 1906) give an account of their more recent experiments bearing on the modes of infection with tuberculosis. It will be remembered that in a previous number they related that adult goats, when fed with tubercle bacilli, by the help of an œsophageal tube, easily became infected, but that the disease attacked not the mesenteric glands, but the lungs. This conclusion was in direct opposition to the view of Von Behring, that tuberculosis of the adult is the result of an intestinal infection received when young. The authors have now performed a similar set of experiments in the case of adult cows, with similar results. The effect of these researches may be summed up as follows:—(1) Animals easily become infected with tuberculosis by the path of the intestines, not only in youth, but in adult life, without the passage of the bacilli through the walls of the intestine leaving very visible lesion; (2) in young animals, the bacilli are usually stopped by the mesenteric glands. Sometimes the infection passes no further, but after a longer or shorter duration, becomes cured. Sometimes, on the other hand, typical lesions appear, followed by a general infection travelling along the lymphatic vessels; (3) in adult animals, the defensive activity of the mesenteric glands being less, the bacilli pass more rapidly into the general circulation; (4) the pulmonary tuberculosis, commonly described as "primary," is most often of intestinal origin; (5) of all modes of tubercular infection, infection by the digestive tube is the most efficacious. R.

NOTE.—*A Summary will appear each week in the following sequence:*—(1) "*Recent Medical Literature.*" (2) "*Recent Surgical Literature.*" (3) "*Recent Gynæcological and Obstetrical Literature.*" (4) "*The Recent Literature of Physiology and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

R. G. BAILEY.—A reference to the recently-issued report of the Army Medical Department will show that about one in five applicants were rejected on the score of defective teeth. There is room for doubt whether this exclusion does not represent a counsel of perfection. There are bad teeth and bad teeth, and the effect on general bodily fitness to a great extent depends on contributory factors, such as food, fresh air, exercise, and, above all, the period of life.

FOOD CONTAMINATION.

A MANCHESTER correspondent has drawn our attention to an article that appeared recently in a local newspaper. The superiority of peas over butcher meat is therein ably advocated, both on the score of cheapness and of absence of contamination. We can only assure our correspondent that the shelling of peas for market purposes is often conducted under revolting conditions of filthiness on the part of the waifs and strays who handle the pods.

MR. CURWEN.—The only cities of the United States of which we have official statistics as to population are:—New York with 4,152,860, Chicago 2,049,185, Philadelphia 1,469,126, Boston 617,950. St. Louis probably comes next to these in point of numbers, and San Francisco closely following before the recent earthquake.

A. B. S. (Burnley).—A new edition of the work has been recently announced. See reference thereto in our "Literary Notes" column.

DR. H. S. T. will receive a private note as soon as the necessary information is obtained. We think, however, it will be in the negative.

THE AMMANFORD COLLIERY POST.

WITH reference to our caution as to the Ammanford Colliery medical appointment we gave from the *South Wales Daily Post* the post was declined by Dr. Martin, of Treorky, but was later accepted by Dr. Scott, of Cwmtwrch.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 11th.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. T. P. Legg: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. C. O. Hawthorne: Pulse Tracings and their Clinical Significance.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. F. Taylor: Medicine. 3.15 p.m. Mr. M. Robson: Surgery. 4 p.m. Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

THURSDAY, JULY 12th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Macnaughton Jones, Dr. J. Aarons, and Dr. C. Maunsell. Papers:—Dr. J. Oliver: A Study of Hydatidiform Mole, with Records of Three Typical Cases. Dr. Macnaughton-Jones:—Remarks on Closure of Small Recto-vaginal Fistula involving the Sphincter.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Mr. H. S. Clogg: Peritonitis in Children.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. G. Rankin: Medicine. 3.15 p.m. Sir W. Bennett: Surgery. 4 p.m. Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Ear and Throat.

FRIDAY, JULY 13th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Card Specimens. 8.30 p.m. Papers: Mr. W. T. H. Spicer: Intraocular Infectives. Mr. A. R. Bralley: Congenital Distichiasis. Mr. C. H. Usher (Aberdeen): A Note on the Chorold at the Macular Region. Annual General Meeting. Election of Officers for 1906-07.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. E. Clarke. Clinique. (Eye).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. R. Bradford: Medicine. 3.15 p.m. Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Skin.

SATURDAY, JULY 14th.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

MONDAY, JULY 16th.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Presentation of Prizes and Unveiling of S. Africa War Memorial by Surgeon-General Sir A. Keogh, K.C.B., at 4 p.m.

Vacancies.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. Applications to the Director, School of Medicine, Cairo, Egypt.

Royal Dental Hospital of London, Mechanical Pupils' Department.—Demonstrator. Salary £120 per annum. Applications to the Dean, 32 Leicester Square, W.C.

Royal City of Dublin Hospital.—Anæsthetist, Pathologist, and Dentist. Immediate application to Mr. G. Jameson, Hon. Sec Medical Board. (See advt.)

Victoria Hospital, Burnley.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Sec., 7 Grimshaw Street, Burnley.

The Hartlepools Hospital. House Surgeon. Salary £100 per annum, with board, washing, and lodging in the Institution. Applications to Robert Edger, Secretary, 15, Town Wall, Hartlepool.

University of Manchester.—Junior Demonstrator in Physiology.—Salary £100 per annum. Applications to the Registrar.

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Required for Railway in South America.—Assistant Medical Officer. Salary £350 per annum. Address, A. R., care of Messrs. Charles Barker and Sons, 8 Birchin Lane, E.C.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications to Edmund Forster, Secretary.

Littlemore Pauper Lunatic Asylum, near Oxford.—Second Assistant Medical Officer. Salary £150 per annum, with furnished rooms and board. Applications to Thomas M. Davenport, Clerk of the Visiting Committee, County Hall, Oxford.

Manchester.—Chorlton-upon-Medlock Dispensary.—Resident House Surgeon. Salary £120 per annum, with furnished rooms and attendance. Applications to the Hon. Secretary.

Appointments.

GRAY, A. M. H., M.D., B.S.Lond., Resident Medical Officer at University College Hospital.

ODGERS, N. B., M.B., M.Ch.Oxon., F.R.C.S.Eng., Assistant Surgeon to the General Hospital, Northampton.

RAMSAY, A., M.B., M.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Leadhills and Wanlockhead District of the counties of Lanark and Dumfries.

RING, C. A. E., L.R.C.P. and S.Edin., L.F.P.S.Glasg., District Medical Officer by the Okehampton (Devon) Board of Guardians; also Certifying Surgeon under the Factory and Workshop Act for the Hatherleigh District of the county of Devon.

ROSE, FRANK A., M.B., B.C.Cantab., F.R.C.S.Eng., Surgeon to the Ear and Throat Department with Charge of Out-patients at the Great Northern Central Hospital.

SMITH, S. MAYNARD, M.B., B.S.Lond., F.R.C.S.Eng., Surgeon in Charge of Out-patients at St. Mary's Hospital.

SUTHERLAND, J. R., M.B., Ch.B.Glasg., Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

WILSON, A. GARRICK, M.B., M.C.Cantab., F.R.C.S.Eng., Surgeon to the Sheffield Children's Hospital.

Births.

BARNETT.—On July 6th, at 23 Hillgrove Road, South Hampstead, the wife of Lawrence Barnett, M.D.Lond., of a daughter.

CUNNINGHAM.—On July 7th, at Firenze, Malone Park, Belfast, the wife of H. H. B. Cunningham, M.D., F.R.C.S.I., of a daughter.

Marriages.

BODINGTON—RIVIERE.—On July 5th, at St. Paul's Church, South Hampstead, Arthur Eaton Bodington, M.A., M.D., of Winchester, son of the late G. F. Bodington, M.D., F.R.C.S., to Theodora, younger daughter of Briton Riviere, R.A., of Flaxley, 82 Finchley Road.

DIXSON—ROBERTSON.—On July 5th, at St. Paul's Church, Brentford, Charles Frederick Lyne Dixson, M.D., M.R.C.S., to Jessie May Robertson, eldest daughter of Mrs. Newcombe, of Clovelly, Boston Road, Brentford.

DRAPER—DIXON.—On July 7th, at St. Matthew's Church, Upper Clapton, John R. Draper, B.A., M.B., B.C. (Cantab.), youngest son of the late Thomas Draper, of Bradley Hall, Eccleston, Lancashire, to Nellie, eldest daughter of Robt. Dixon, Alconbury Road, Upper Clapton.

GRIFFITH—GOODE.—On July 5th, at the Parish Church, Hampton, Richard, elder son of Samuel Griffith, M.D., J.P., Portmadoc, North Wales, to Mary Greayer (Cissy), elder daughter of John Charles Goode, of Castle House, Hampton, Middlesex.

HAMMOND-SMITH—PARAMORE.—On July 4th, at Christ Church, Woburn Square, London, Arthur Hammond Smith, L.D.S., of Anerley, King's Road, Reading, to Florence Maud, the younger daughter of Richard Paramore, M.D., of 2 Gordon Square, London.

Deaths.

HILL.—On July 6th, at St. Keverne, Lymington, Hants, William Robinson Hill, M.D., J.P., aged 70 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, JULY 18, 1906. No. 3.

NOTES AND COMMENTS.

An Unworthy Trick.

THE police news of several London dailies recently contained the announcement that a doctor, whose name and address were given, had been fined by the magistrate for being drunk and disorderly. The prisoner, we are glad to say, was not a member of the profession, but by giving the name and address of an actual person he was guilty of a peculiarly mean and despicable fraud, and one that we say emphatically should be impossible under any police system. It is difficult to impute blame to the reporters, who merely transmitted in the ordinary course of their duties the name as given in Court; and, indeed, if the unworthy scoundrel who personated the doctor were discovered, it is by no means certain that an action for damages would lie against him. But it surely argues a culpable laxity on the part of the police staff that they should be satisfied with any name given them by a casual "drunk," and the least that they could be expected to do would be to assure a prisoner that he would remain a prisoner till he proved his identity. It is intolerable that the good name of a member of an honourable profession should be liable to be besmirched by any ruffian who gets into trouble by his own folly.

Doctor-Badgering.

ANOTHER hiatus in the police system is its inability to arrange for proper reports being made on patients in hospitals who are required as witnesses. There seems to be no alternative to summoning the house-surgeon to give evidence as to their state of health, which is generally inconvenient, but at least carries a fee with it, or sending a police-officer to make informal inquiries at any hour of the day or night that happens to suit his own convenience. Needless to say, no fee is offered for such visits. Now, house-surgeons are busy men, whose time is fully occupied with important duties, and it is unfair that the State for its own purposes should countenance a system of badgering when proper arrangements could easily be made.

A Case in Point.

LAST week at Birmingham, in the course of a prosecution for malicious wounding, the stipendiary wishing to know the condition of the wounded man, ordered a police constable to make immediate inquiries at the hospital. Dr. Clarke, very properly, refused to disclose information about his patient in this informal way, but intimated that he was prepared when properly summoned to give the necessary evidence. The magistrate, on receiving this reply, sent the constable a second time, and when Dr. Clarke was found to maintain his attitude of reserve, the stipendiary remarked that he would lay the matter before the Board of the Hospital. If as a lawyer, he does not know that Dr. Clarke was acting strictly on legal grounds, the magistrate might, as a man of the world, be aware that gentlemen with responsible duties do not wish to be baited by irresponsible constables. A proper medical report-form carrying a reasonable fee, should be available for such purposes.

Legal Incredulity.

THE law is often said to be no respecter of persons, and it would seem at least that many lawyers are no respecters of doctors. In giving evidence, even in the High Court of Justice, as to a person's inability to appear, a doctor is frequently subjected to ruthless cross-examination by the opposing counsel. It is natural that when an important witness is unable to attend, the side that suffers should say that the illness is greatly exaggerated or altogether feigned, but it is not right that an honest medical man should have to bear the brunt of their discontent. Last week, in the case of the bankruptcy of Mr. F. Horner, Dr. Pelham Maitland had to attend and endure a severe cross-examination, punctuated with laughter, as to the debtor's inability to be present. Fortunately, an independent consulting physician had seen Mr. Horner with Dr. Maitland, and the Registrar was eventually satisfied, but it is difficult to see why the Court should not have its own medical official to report on such cases.

Telephonic Consultations

ALTHOUGH the telephone nuisance has not reached so acute a phase in this country as in others, it is still at times sufficiently annoying. In Vienna the abuse of the system has reached such a point that, in order to put an end to a doubt as to whether a medical man was entitled to charge a fee for advice given by telephone, a case was brought into Court. In this case the patient had on several occasions sought advice over the telephone, sometimes even at night, and for such advice he refused to pay. The result of the case is satisfactory to the profession in Vienna, as the judge decided that advice must be paid for whether given through the telephone

by letter, or in the consulting-room. The special knowledge acquired by a practitioner must not be made the subject of sweating. As it is an invidious matter for one medical man to charge for telephonic advice unless his colleagues all do the same, we learn that it is the intention of the branch division of the medical councils in Vienna to compel their members to charge for such consultations.

Hospital Administration Difficulties.

A CASE illustrating the difficulties of isolation hospital administration was tried at Birmingham County Court last week. A working photographer who had five children, and earned three guineas a week in wages, was summoned by the King's Norton Urban District Council for £30 5s. for seventeen weeks' maintenance of his child in their hospital, while she was suffering from scarlet fever. The local authority in whose district the father lived were apparently unable to make arrangements themselves for receiving the child, and she was consequently sent to the King's Norton hospital. The father being under the impression that the treatment would only last six weeks, seems to have consented to pay £1 15s. a week, and when the bill came in, he found he was saddled with £30 5s.—a serious sum for a man of his means. In the event, the jury, taking a lenient view, let him off with ten guineas, though he would appear to have been liable for the larger amount. Though no doubt there was some misunderstanding, the case undoubtedly presents features of considerable hardship.

LEADING ARTICLE.

HOSPITAL FUNDS AND AMALGAMATION OF SPECIAL HOSPITALS.

LAST week the London City Orthopædic Hospital formally accepted the amalgamation scheme which has been so long urged by the Hospital Sunday Fund. As our readers may remember, the Royal and the National Orthopædic Hospitals had previously joined hands. With the general principle of amalgamation we have little concern, for there is obviously much to be said in favour of the economy of administration that must necessarily be effected by a wise centralisation But approval must, as a matter of ordinary prudence, be qualified with certain clearly-defined conditions. The Metropolitan Hospital Sunday Fund is obviously not justified in forcing a policy of amalgamation upon a group of hospitals without accepting the responsibilities involved in such a proceeding. In the particular case of the London Orthopædic hospitals we venture to think that the public, no less than the medical profession, are entitled to ask whether the Sunday Fund can justify their intervention. First of all, the financial management of the Royal had been the subject of unsparing criticism for several years. The management, under the chairmanship of Mr. H. H. Marks, decided to sell the enormously valuable freehold site of the Hospital, and were casting about for another site, when the amalgamation scheme enabled them to hide their failure in finance by fusing their funds with those of the National. The former site of the Royal Orthopædic in Oxford Street is now covered with expensive flats and shops, but the freehold endowment of this is gone, or will shortly be gone, for ever from the cause of medical charity. Was the Hospital Sunday Fund in full possession of the facts in connection with the sale or the proposed sale of the site of the Royal Hospital? Do they approve the financial judgment of Mr. Marks' committee in the affair? If not, how could they urge amalgamation without an intimate knowledge of the finances of the hospitals involved? The attention of the Sunday Fund was repeatedly called to the proposed sale of the site in the columns of THE MEDICAL PRESS AND CIRCULAR. It is obvious that if the Fund do not inquire carefully into the affairs of institutions upon which they are urging so all-important a step, their amalgamation policy may at any time be made the stalking horse of fatuous financial blunderers. But whatever may be said as to finance, there is another absolutely unjust condition of hospital life that the Hospital Sunday Fund must consider if they wish to maintain their reputation for justice and independence. We refer to the exclusion of holders of Scotch and Irish medical qualifications from hospital posts. The National had that extremely offensive and obnoxious condition as one of their bye-laws, the Royal had not. We believe that the two amalgamated hospitals admitted an Edinburgh Fellow, one of the staff of the Royal, for a limited period as surgeon. We think we are accurate in saying, however, that the amalgamated staff will in future exclude all save London diplomates. At any rate, we hold it to be the bounden duty of the Hospital Sunday Fund to see they have no hand in an amalgamation scheme that permits the perpetuation and extension of so gross an injustice. How does this exclusion affect the City Orthopædic Hospital? In spite of protests that all is well, and that the Charter provides for justice, the opinion of the medical men concerned is clear enough. Mr. John Poland, as a Fellow of the London College of Surgeons, is entitled to a place on the amalgamated staff of the three hospitals. Two of his colleagues, however, able and experienced men though they be, will be excluded because they hold Scotch qualifications. The City Orthopædic Hospital have appended to their acceptance of amalgamation a simple note expressing a hope that their medical staff will be elected instead of the strong, sturdy protest against the injustice of excluding from public posts honourable members of an honourable profession for so poor a reason as the trade union protection of the London Colleges. In the name of ordinary justice we beg the Hospital Funds to see fair play in this matter, and to take care they do not become the cats-paws of self-seeking corporations. It is to be hoped that Scottish and Irish graduates and diplomates will take steps to educate the public on this matter. We feel certain that neither

His Majesty King Edward nor the Prince of Wales would knowingly sanction the perpetration of so great an injustice by the Hospital Sunday or any other Fund under their patronage.

NOTES ON CURRENT TOPICS.

The Royal Victoria Infirmary.

THE magnificent new buildings of the Royal Victoria Infirmary at Newcastle-upon-Tyne were last week formally opened by His Majesty the King. The cost of the Institution has been £300,000, of which £100,000 was given by the late Mr. John Hall, £100,000 by Lord and Lady Armstrong, while the remaining £100,000 was collected by Sir Riley Lord in Newcastle and the district. The site is on the Leazes section of the Town Moor, and of its ten acres the greater part is covered by buildings. The Infirmary is a handsome structure of red brick and sandstone, built on the pavilion system from the designs of Mr. W. T. Newcombe, F.R.I.B.A., and Mr. H. P. Adams, F.R.I.B.A. It has eight ward pavilions, containing 20 wards and 450 beds, the latter being about 200 in excess of the number in the old infirmary. The administrative block occupies a central position, in which ample accommodation is made for committee, honorary staff, students and residents. The wards are arranged to hold 24 beds, each with an allowance of 1,500 cubic feet air space to each bed. There is no need to go into details of construction beyond saying that the whole building is fitted out in a very comfortable style upon the most modern scientific principles. The children's ward contains 46 beds, and is beautifully decorated. The new Infirmary is a building of which the citizens of Newcastle may well be proud.

Mr. Haldane's Scientific Methods.

MR. HALDANE, though a lawyer by profession and a Minister for War by the sport of political circumstances, is a scientific man by bent and education, and a scientific man in the broadest sense of the word. On Friday last, after distributing the prizes at the London Hospital, he gave an address as refreshing to the scientific portion of his audience as stimulating to lay readers. Mr. Haldane recognises that real advance can only be attained rapidly and surely by painstaking elucidation and estimation of the factors of a problem, and the marshalling of these according to a carefully co-ordinated plan. To work thus is to work on scientific lines, to conserve energy, and to beat competitors. This great principle, which should be acknowledged and acted upon in every department of national life, Mr. Haldane showed was nowhere more important than in the study and practice of medicine, and nowhere was it so well recognised. The old ideals and the old methods—empiricism and "muddling through"—may have done well enough in our ancestors' time, but we now live in a new epoch, in which new ideals and new methods are essential to success, and Mr. Haldane sees them sinking more deeply into national life and taking stronger hold of people generally, with each succeeding year. But it was pointed out that no nation stood more in need of so thorough an impregnation with science as the British, for with their extraordinary energy, if an error be committed, they go far before they find out they are wrong, and it is not always easy to retrace their steps. It is a sign of the times, and a comforting one, too, that an important position in the Cabinet, should at last fall to a man to whom modern science is an actual and living guide, and not a tiresome excrescence on the body politic.

International Notification of Disease.

AT the Congress of the Royal Sanitary Institute last week two interesting papers were read in the Preventive Medicine section, both suggesting that a wider view should be taken of the occurrence of infectious disease in various countries. The first of these papers was read by Dr. Fremantle under the title of "Public Health and the Imperial Conference," and in it he argued that the figures and facts about infectious diseases should be freely and officially transmitted between all parts of the Empire, not only as end in itself, but with a view to bringing foreign countries eventually within the arrangement. Dr. Walford's paper—"An International System of Notification of the More Serious Infectious Diseases"—went further, and proposed that all countries should unite in the scheme with a view to mutual benefit. From the strictly scientific point of view, there can be no doubt that much valuable information would be afforded to the epidemiologist by the collection of all notification returns, and the expense would be but small, but it is difficult to argue that any great diminution in the incidence or international exchange of infectious diseases would be likely to occur. Plague and cholera, the two diseases Great Britain is really afraid of importing, are already notifiable between nations, but it is questionable whether, if other diseases were added to the list, advantage might not be taken of the fact seriously to injure British shipping. International notification argues great international confidence, and though the world is becoming more civilised, and Powers are not so shy as they were, there are some at least who have not shown a wholehearted longing to forward British commerce. The British delegates to the 1903 International Sanitary Congress were, we know, opposed to the idea of an international bureau.

Overworking of Nurses.

WE have before us a report of a meeting of the Board of Guardians of the Aston Workhouse Infirmary held last week, containing statements which if accurate, disclose a state of things about which it would be difficult to speak too strongly. A Mr. W. H. Ayles, speaking on the report of the House Committee, said that at the present time a night attendant was in charge of two wards containing respectively eighty and eighty-one patients, and that when the nurse was relieved the patients

were either left in charge of an inmate, or remained totally unattended. Among the 161 cases there were forty-six acute epileptics, some of whom had as many as twelve fits in a night. Some of the patients suffered from dementia and were occasionally violent. The representative of the Committee said that he had nothing to add to what had been said at a former meeting, and that he was prepared to accept full responsibility. The chairman of the Board remarked that he hoped the representative would not regret it, and the reply he received was that the "committee were not so timid as some people." Later it was suggested that an independent committee of inquiry should be appointed, and the chairman of the Infirmary Committee welcomed the suggestion, and admitted that more nurses were needed. He mentioned that the previous week a patient died in great suffering, while the nurse was attending to another seriously-ill case. If the facts be as stated, the sooner an independent committee of inquiry be appointed the better, for we never remember to have read of any worse case of understaffing since the horrors of the Crimean war, and we trust that the attention of the Local Government Board will be duly drawn to the question.

The Salt Sea as a Skin Irritant.

MEDICAL men are often asked as to whether it is wise or not for patients having a sensitive skin to visit the seaside. When there is any acute inflammatory condition, or where the skin is liable to sudden storms of eczematous type it is simply asking for trouble—to use the graphic language of the East End—to visit a salt-laden environment, Then, again, a chronic malady may sometimes be lighted up thereby into an acute fiery outburst. Yet there can be little doubt that on the whole the salt necessarily encountered in the neighbourhood of the sea is a wholesome tonic to the skin. At times—as we all know—it acts as a strong irritant to the healthiest skin, which turns a rich red or brown, and proceeds to peel off incontinently. After this first protest against an unaccustomed irritant, the rebellious skin soon settles down into contented restfulness. Quite possibly, a similar healthy reaction would follow in many so-called "delicate" skins, and the first original damage due to sun and sea-salt could be overcome. To the robust Philistine, both of those powerful seaside irritants act simply as incentives to healthy action, not only of the skin, but of every other organ of the body.

The Dublin Water Supply.

WE published last week a letter in which Dr. McWalter, of Dublin, drew attention to the necessity of periodical bacterioscopic examinations of the water supply of Dublin. There is no doubt that Dublin has in the Vartry water a remarkably pure supply, so pure indeed that in the bacteriological laboratories in Dublin, ordinary tap water is regarded as sterile. This reputation of the Dublin water has probably given those responsible for the Health of Dublin a false sense of security, and the danger to which Dr. McWalter alludes is a very real one. The catchment area has recently been much enlarged, and during the next few months hundreds of workmen will be employed in building reservoirs, and in other work at Roundwood. It is obvious that the water-supply will be exposed to every risk of contamination, and in case of any one of the workmen suffering from typhoid fever or other water-borne disease, the health of the citizens of Dublin will be in imminent danger. It is to be hoped that by having the workmen at Roundwood under efficient sanitary control, every means will be taken to prevent contamination. Nevertheless, if contamination occurs it is obvious that it ought to be discovered at the earliest possible moment. To bring this about, periodic bacterioscopic examination is imperative. We trust that Dr. McWalter is in error when he says that "the Dublin Corporation cannot be got to see the necessity of it." The death-rate of Dublin is sufficiently high without such an epidemic as any carelessness at the present time may bring about.

The R.C.S. and Midwives.

AT the quarterly meeting of the Council of the Royal College of Surgeons of England held last Thursday, the various officers for the year were elected and the professors duly appointed. It was then moved by Mr. Ward Cousins, and seconded by Mr. Godlee that a resolution in favour of the adequate payment of medical men for assisting midwives in dangerous cases be passed. That the College which, up till the present, has so studiously avoided rendering help to its members should now depart from this traditional policy, and actually step into the arena of medical politics, is a sign of grace no less welcome than unexpected. It is perhaps significant that the resolution was proposed by a provincial fellow, but, once proposed, it would have been difficult for the Council to have refused to adopt it. Nevertheless, we congratulate the Council on its first effort towards assisting its *alumni*, and we particularly congratulate Mr. Ward Cousins on the success of his motion. Perhaps some day the College may see its way to bolder things even than registering a pious resolution.

Curious Generosity.

THERE is an odd circumstance connected with the lamented death of that brilliant journalist and politician, Mr. Pakeman, of the Transvaal. Vigorous partisan though he was, Mr. Pakeman possessed the rare power of making his opponents not only respect but actually like him warmly. It is stated that when it was known a little while ago that he was suffering from cancer, one of the Rand millionaires, a well-known sportsman, whom he was constantly opposing in politics, said that he had seen in a newspaper that a new cancer cure had been brought out in America, and he would be glad if Mr. Pakeman would, as his guest, go to New York and undergo the treatment. Though this offer speaks well for the millionaire's goodness of heart, it throws into relief the untold harm that is and may be done by the irresponsible press-booming of pretentious "cures."

The Dangerous Performances Bill.

THE showmen of Merrie England are up in arms now that their vested right of risking the lives of performers is threatened. For many years THE MEDICAL PRESS AND CIRCULAR has advocated the need of putting a stop to these dangerous diversions. From time to time all kinds of terrible deaths have been commented on in our columns. Now it has been some unfortunate performer killed by a lion, alligator, or other wild beast, or at another some luckless wight mangled by a fall in looping the loop, diving from a lofty roof, or some other mad feat. The very existence of deadly performances of the kind shows that there is fascination about the thing which appeals to some deeply-rooted instinct of mankind. Its nature is somewhat akin to the old Roman love of the gladiatorial show and the modern Spanish bull-fight. Anyway, the showmen recognise the value of risky feats in the playbill. Last week they went in formal deputation to Mr. Herbert Samuel, Under Secretary for Home Affairs, to protest against the passing of the Dangerous Performances Bill. Their chief ground was that during the last five years only two serious accidents had happened in 7,800,000 performances. Those two, however, were, in our opinion, the result of totally unjustifiable risks. ———

Death in the Serviette.

AN outcry has been raised on the strength of a pronouncement by Professor Kron, against the necessary, if not harmless, serviette which is the badge of the waiter tribe. In fact, it is the question of harmlessness which is at stake. Is the waiter's serviette a means of conveying disease, or is it not? The probability is that cloths equally dirty, indeed much more so, are used to wipe dishes and plates in the kitchen, but the eye of the restaurant customer not seeing them, his heart does not grieve. The serviette of the waiter, however, is obtrusively obvious, and if the customer, be he professor or man-in-the-street, see it used successively to polish the leg of the table and to give the final touch to his tumbler, the gorge is apt to rise. Everything that makes for cleanliness in habit naturally has the support of the medical profession, and though one should not anticipate any startling changes in the Registrar-General's returns if the serviette were abolished, it might reasonably be replaced by the Japanese paper serviettes which are too cheap to be worth using twice, and too flimsy to stand much that is now done by the linen article.

PERSONAL.

ON July 11th King Edward visited Newcastle-on-Tyne, where he formally opened the new Royal Victoria Infirmary, of which His Majesty, when Prince of Wales, laid the foundation stone on June 20th, 1900.

THE Congress of the Royal Sanitary Institute was opened on the 9th inst. by the Lord Mayor of Bristol, and the Presidential Address was delivered on the evening of the same day by Sir Edward Fry.

SURGEON-GENERAL SIR A. KEOGH, K.C.B., Director-General of the Army Medical Department, presented the prizes and unveiled the South African War Memorial, at St. Mary's Hospital School, London, on Monday last. ———

THE sixty-fifth annual meeting of the Medico-Psychological Association will be held at 11, Chandos Street London, W., on the 26th and 27th instant, under the presidency of Dr. Robert Jones. The annual dinner will take place on the evening of the 26th at the New Gaiety Restaurant.

DR. LENNOX LINDLEY, formerly Assistant Physician, has been appointed Physician-in-Chief to the Shah of Persia, a post recently held by Dr. Schneider, a French physician.

SIR JAMES CRICHTON-BROWNE will deliver the Opening Address to the students of the Leeds Medical School in October next.

A PRESENTATION consisting of a handsome marble clock and ornaments was made to Dr. Morris, medical officer of health for Neath, on the occasion of his wedding. The Mayor on behalf of the officers of the Corporation made the presentation.

MME. CURIE, who was approached with reference to a joint testimonial to her husband and herself, has replied to her admirers that M. Curie was so much opposed to the usual ways of honouring the dead that she hopes no such project will be entertained.

DR. Dow, on the occasion of his retirement after fifty years' practice in Dunfermline was last week presented with a handsome silver testimonial from his friends and patients.

To celebrate the twentieth year of his Professorship of Gynæcology, Dr. Samuel Pozzi was presented with a specially designed gold medal, and a "golden book," containing unpublished articles on gynæcology by leading men. Dr. Debove, Dean of the Faculty of Medicine at Paris, took the chair at the ceremony.

PERMISSION has been granted by the King to Dr. H. Nolan, medico-legal adviser to the Egyptian Native Tribunal, to accept the Order of the Medjidieh, 3rd Class, conferred on him by the Khedive.

THE Government grant for successful vaccination has been awarded for the second time in succession to Mr. Legh Richmond Marshall, Public Vaccinator for the Mary Tavy District of the Tavistock Union.

DR. EDWARD CARNELL was recently presented with a testimonial in the shape of a handsome paper-knife by the members of the Harrogate Branch of the St. John's Ambulance Association, as a token of their gratitude for his services.

THE King has granted permission to Dr. W. St. C. Symmers, formerly Professor of Pathology in the Egyptian School of Medicine, and now Professor of Pathology in the Queen's College, Belfast, to accept the Order of Medjidieh, Third Class, and the Order of the Osmanieh, Fourth Class.

DR. JOHN F. W. TATHAM, M.D. (Univ. Dub.), M.D., F.R.C.P.Lond., Superintendent of Statistics, General Register Office, London and President of the Epidemiological Society, has been elected an Honorary Fellow of the Royal College of Physicians of Ireland.

DR. HOWARD KELLY, who has just added to his literary output a memorial volume on the work of the late Dr. Walter Reed, is, we believe, to visit this country again in the autumn. Dr. Reed, it will be remembered, died during his strenuous efforts to work out the pathology of yellow fever.

D

A CLINICAL LECTURE
ON
PSOAS ABSCESS: ITS NATURE AND TREATMENT, WITH NOTES OF AN ILLUSTRATIVE CASE.*

By C. YELVERTON PEARSON, F.R.C.S., F.R.U.I.,
Professor of Surgery, Queen's College, Cork.

GENTLEMEN,—The patient to whose case I wish to direct your attention to-day is one on whom you saw me operate for psoas abscess just three weeks ago.

The case is one which presents some peculiar points of interest:—(1) He is older than the usual class of such cases we meet with; (2) he never gave any indication that he had suffered from spinal mischief; (3) his symptoms were referred almost entirely to the region of the hip-joint; and, (4) a number of the senior students, to whom I submitted the case at a recent clinical examination, all diagnosed hip-joint disease; whilst only one of the five who examined him recognised that he was suffering from psoas abscess. Before dwelling on the aspects of this particular case I think it well to review the subject of psoas abscess in a general manner.

Definition.—Psoas abscess is a collection of pus, confined in the first instance by the fascial sheath of the psoas magnus muscle, extending after a time beneath the fascia of the iliacus and later on in other directions. As ordinarily met with it may be defined as a chronic abscess in the psoas sheath resulting from and symptomatic of tubercular osteo-myelitis of the lower dorsal or the lumbar vertebræ.

Mode of Origin.—Suppuration may arise within the psoas as the result of injury and idiopathic infection, with pyogenic micro-organisms; it usually results from spinal caries of the lower dorsal or upper lumbar vertebræ. It is not often met with before puberty, generally between that period and thirty years of age; it is more common in males than in females, and is more likely to form in spinal caries if the patient has been going about during the early stages of the disease. Again, a psoas abscess may result from suppuration of tubercular lymphatic glands in the posterior mediastinal space, or in rare instances be due to the escape of pus from an empyema into the posterior mediastinum The matter in such cases entering the sheath of the psoas beneath the *ligamentum arcuatum internum* of the diaphragm. An iliac abscess proper may, by extension, involve the psoas, or an abscess in the psoas may be the result of sacro-iliac disease; finally, in exceptional instances, the sheath of the psoas becomes involved by extension from disease of the hip joint first to the bursa beneath the psoas tendon and from that to the sheath of the muscle itself.

Anatomical Characters.—The course of a psoas abscess will be best understood by first considering the disposition of the fascia forming the sheath of the muscle. It is derived from the fascia iliaca of the abdomen. This is a dense fibrous membrane which covers the iliacus muscle, being attached externally to the whole length of the inner border of the crest of the ileum, passes over the psoas and is attached internally to the brim of the pelvis. Below, it is intimately connected with the portion of Poupart's ligament which is external to the line of the external iliac vessels. Behind the vessels it descends into the thigh and forms the posterior wall of the femoral sheath. At the inner side of the vessels it is attached to the ilio-pectineal line behind the conjoined tendon. It becomes continuous with the transversalis fascia on the inner and outer sides of the external iliac vessels. The portion in relation with psoas magnus muscle is attached internally to the base of the sacrum, the upper and lower margins of the bodies of the lumbar vertebræ and the intervertebral discs, thus forming tendinous arches over the concavities of the bodies of the vertebræ. These arches give origin to the psoas muscle, and transmit the lumbar vessels and branches of the sympathetic nerve. Above, it forms the *ligamentum arcuatum internum.* Below the crest of the ilium the psoas portion of the iliac fascia becomes continuous externally with the portion which covers the iliacus muscle; the two muscles being only separated by delicate connective tissues. Above the iliac crest it is attached externally to the anterior layer of the lumbar fascia near the tips of the transverse processes of the vertebræ.

At the point where the iliac fascia is attached to the ilio-pectineal line it is indirectly continuous with the pelvic fascia. Internal to the psoas it is also attached to the capsule of the hip-joint and to the upper ramus of the pubis, becoming continuous with the pubic portion of the fascia lata. Opposite the outer half of Poupart's ligament the iliac and transversalis fascia blend, and are there closely united to that ligament. Beneath the inner part of the ligament they do not blend but are separated by the blood vessels and continue downwards upon them to form the femoral sheath. Below Poupart's ligament the iliac fascia continues to cover the psoas and iliacus muscles and the anterior crural nerve.

In caries of the upper and middle dorsal when pus forms, owing to the resistance offered by the parietal pleura, it is usually directed backwards through the intercostal spaces following the course of the dorsal branches of the intercostal vessels and gives rise to a dorsal spinal abscess. In the lower dorsal region, owing to the absence of the pleura the pus passes downwards by the side of the aorta and enters the sheath of the psoas on one or both sides beneath the *ligamentum arcuatum internum.* Suppurative caries in the dorso-lumbar or lumbar region will give rise to a lumbar abscess when the pus is formed behind the attachment of the anterior layer of the lumbar aponeurosis; to a psoas or ilio-psoas abscess when occurring beneath the limits of attachment of the iliac fascia; and to a pelvic abscess when situated between or below the internal attachment of the iliac fascia on either side. When pus enters the sheath of the psoas the matter passes down the whole length of the muscle destroying many of its fibres partly by suppuration and partly by ulceration. Later on it extends outwards beneath the iliac fascia, destroying much of the substance of the iliacus muscle, and becomes an ilio-psoas abscess. The exact situation at which this extension occurs is not very clear. Owing to the disposition of the fascia, which I have already described, extension might occur at any point below the iliac crest. But in all probability it does not usually take place until the matter meets with the increased resistance offered by the narrowing of the sheath where the two muscles become conjoined.

A psoas abscess is usually more or less multilocular It may be single or double. The double variety, as I have already indicated, usually resulting from disease in the lower dorsal region, but possibly originating, in some instances from bilateral disease of the lumbar vertebræ.

The contents of the abscess vary in character, but as in the case of chronic abscesses in general, true pus is absent. They may be serous or sero-purulent with caseous masses, and in most cases fragments of carious and necrotic bone. In old-standing cases, owing to

*Delivered in the North Charitable Infirmary, Cork, May 28th, 1906.

the absorption of the more fluid contents, the residuum may consist of cheesy and calcareous matter.

Tubercle bacilli can occasionally be detected, though the fluid usually proves sterile on attempts at culture.

Course and Terminations.—When following an anatomical course, a psoas abscess leaves the abdomen beneath Poupart's ligament outside the vessels, it then passes beneath them towards the lesser trochanter. If the iliac portion passes out separately, it forms a swelling external to the artery. If the swelling is large it may conceal the femoral vessels; sometimes it pushes them forwards so that the vein is compressed and the artery beats subcutaneously. In some instances the abscess may expand in Scarpa's space forming its own sac, and then varies much in character. When small, it may simulate a femoral hernia; when large, it may appear double from an oblique depression produced by the crossing of the Sartorius muscle. It may then pass outwards along the course of the external circumflex vessels under the *tensor fascia femoris* and open over the great trochanter.

Usually after reaching the thigh the abscess extends downwards on the outer side of the femoral vessels till it reaches the origin of the profunda artery, and following the course of that vessel passes under the femoral vessels.

It then continues its course beneath the adductor longus forming a large swelling at the inner side of the thigh, having the adductor longus in front, the adductor magnus behind it, and the gracilis stretched over its inner side. It often happens that processes extend from the main cavity along the branches of the profunda, the most common being one following the internal circumflex winding round the neck of the femur and passing backwards through the interval between the quadratus femoris and adductor magnus, and eventually pointing in the interval between the ischial tuberosity and the great trochanter. As a rule the abscess does not extend beyond the upper part of the thigh, but it may extend to the popliteal space, down the back of the leg, and even along the posterior tibial vessels as far as the heel.

A typical and fully developed psoas abscess consists of four principal parts, a narrow track in the upper part of the psoas, an expanded sac in the iliac fossa, another narrow portion beneath Poupart's ligament, and a large cavity on the upper and inner part of the thigh.

The favourite situation for a psoas abscess to point is in the upper adductor region; it may, however, point in many other situations some of which I have already indicated. Occasionally, it points above Poupart's ligament, above the iliac crest, or in the lumbar region. It may open into a viscus such as the bladder or bowel. It has been known to open into one of the large arteries (aorta or iliac) in its vicinity. In exceptional cases by following the course of the lumbo-sacral cord it may reach and pass out through the great sacro-sciatic foramen and form a gluteal abscess. It is stated that a psoas abscess may pass the pelvis by raising the attachment of the iliac fascia from the brim of the pelvis and passing down on the outer aspect of the pelvic fascia reach the ascro-sciatic foramen or the ischio-rectal fossa. Owing to the very firm attachment of the fascia at the pelvic brim I believe this to be an exceedingly rare occurrence. In the majority of cases where pus makes its way into the pelvis as the result of carious disease in the lumbar region, it does so by passing down behind the peritoneum in the interval between the origin of the psoas muscles of opposite sides over the promontory and along the concavity of the sacrum till it reaches the fascia covering the pyriformis muscle, after which it may pass outwards through the sacro-sciatic foramen or in other directions.

A psoas abscess may gradually subside owing to absorption of the more fluid contents and the deposition of earthy salts in the caseous material. Such dried up abscesses sometimes suppurate later on and give rise to what has been termed a residual abscess by Paget. When a psoas abscess bursts spontaneously it usually does so through a small opening: a gush of seropurulent fluid takes place and the opening becomes blocked with cheesy flocculi; these after a time are displaced and a fresh escape of fluid occurs. In this way gradual evacuation may take place without the admission of infective micro-organisms and recovery ensue without constitutional disturbance. When free evacuation occurs or is brought about in the absence of aseptic precautions infection of the sac takes place, followed by acute suppuration with its attendant evils of pyrexia, sapræmia, possibly pyæmia, or a prolonged course of suppurative fever ending in exhaustion or albuminoid degeneration. Such are the natural courses and terminations of this affection.

Diagnosis.—We must now consider the question of diagnosis. This is usually not a difficult matter in fully developed cases, but for its most successful treatment the affection should be recognised whilst intra-abdominal. Subjective symptoms may be absent altogether the extra-abdominal tumour first attracting attention. Early symptoms depend upon the irritation of the lumbar nerves close to the spine which may give rise to pain in the lumbar or iliac regions, or in the course of the anterior crural or sciatic nerves; pain in the region of the hip or sacrum; inclination forwards when standing; internal rotation of the thigh, inability to completely extend the limb, &c.

Inspection and palpation reveal the presence of an elongated vertical swelling in the lumbar region extending into the iliac region or as far as Poupart's ligament. It is elastic or fluctuating, dull on percussion, does not roll from beneath the fingers or alter its position with the posture of the patient, and may be associated with a swelling of similar character in the iliac fossa. Examination of the spine will usually afford evidence of Pott's disease.

When the abscess becomes extra-abdominal, there is a fluctuating swelling in the upper part of the thigh which has an impulse on coughing, is incompletely reducible, and the sense of fluctuation can be transmitted from the portion below to the portion above Poupart's ligament.

The intra-abdominal form of psoas abscess has to be differentiated from overloaded bowel, from iliac or perityphlitic abscess. The extra-abdominal swelling from hernia, from abscess due to hip disease and from the various swellings which may occur in Scarpa's triangle, &c. Time does not permit me to enter into the distinguishing characters of each of these affections, so that I must pass on to the subject of treatment, but before doing so I shall relate the particulars of the case now under consideration, for the notes of which I am chiefly indebted to the observations of those of you who examined the patient previous to operation.

History.—The patient, a farmer, æt. 24, of fairly healthy aspect, was sent to me by Dr. Wm. MacSweeney of Killarney on April 30th. He first complained of pain in the right hip three months ago. He had three or four attacks of pain shooting down to the knee and foot. There was no tenderness over the course of the sciatic nerve. Three weeks ago he began to limp on the right leg and had to give up work. There was no history of injury nor of any previous illness. The family history is good.

Physical Examination.—The patient stands with his right heel raised, the right foot slightly advanced and the toes slightly everted, the hip is very slightly flexed and the pelvis slightly lowered on the affected side.

When lying down, complete extension of the limb produces an almost imperceptible degree of lordosis. Careful measurement from the anterior superior iliac spine to the tip of the internal malleolus shows no difference in the length of the limbs of opposite sides. Measurement of the circumference of the thighs shows no evidence of wasting. The right hip can be moved in all directions with only a slight degree of pain on complete extension or abduction. The pelvis does not move with the thigh. There is no pain produced by

hitting the heel in an upward direction or on pressing the iliac crests together. Some pain is felt on pressing over the great trochanter, but this is superficial in character and follows the course of the cutaneous nerves.

Pain is also produced by pressure on the anterior crural nerve. There is a slight fulness immediately below Poupart's ligament. A marked swelling is felt above Poupart's ligament in the iliac fossa and extending up to the ribs on the right side. This is elastic, slightly fluctuating and offers marked resistance to pressure as compared with the opposite side. No resonance on percussion is present on the right side, except beyond the limit of the swelling. On examination of the back a distinct prominence of the spine of the eleventh dorsal vertebræ is perceptible. There is no tenderness on pressure or percussion over any portion of the spinal column, nor any evidence of active spinal mischief.

It was only by the most careful cross examination that a history of pain in the back and along the course of the lower ribs was elicited. This was noticed three years ago, but did not interfere with the patient following his usual occupation.

Diagnosis.—As I pointed out to you, previous to operation, the symptoms and physical signs justified the diagnosis of psoas abscess dependent on old standing caries of the lower dorsal vertebræ which had become quiescent. The freedom of movement at the hip-joint combined with the absence of wasting of the muscles, and of marked lordosis excluded hip-joint disease.

Treatment.—The patient was operated on May 7th, in the following manner :—An incision was made four inches in length commencing about an inch below, and internal to the anterior uperior iliac spine and terminating below the twelfth rib. All the muscles were divided to the full extent of the superficial incision, then the fascia transversalis ; the peritoneum and intestines were now pushed forwards and inwards, the iliac fascia was pierced with a pair of sinus forceps, and, on opening the blades, pus, of the usual character found in chronic abscesses, escaped freely. Two fingers of the left hand were then introduced, the opening in the fascia extended and the cavity carefully explored in every direction. It was then thoroughly flushed out with a hot solution of mercuric biniodide 1 in 2,000, all débris and caseous material being removed with the aid of the fingers. The vertebræ were carefully explored with the fingers and probe, to ascertain the presence of existing disease, with negative result. The entire cavity was now carefully wiped out with pieces of dry sterile gauze held in sponge forceps. After this, the interior of the cavity was carefully swabbed over with a 1 per cent. watery solution of iodine. Six deep sutures of silk-worm gut were passed through all the divided strata. Before these were tied careful pressure was made over the entire abscess sac so as to bring its walls in contact and expel any air. The sutures were then tied, a dressing of dry sterile gauze was applied over the wound, and pressure was maintained by means of pads placed over the line of the right semi-lunaris and iliac fossa.

You now see that since the operation there has been no disturbance of temperature save a rise to 100° F. during the first twenty-four hours due to aseptic fever, resulting from the necessary but slight extravasation of blood. The wound is perfectly healed, the sutures have been removed, and there is no evidence of refilling of the cavity. (*a*)

I shall now enumerate and briefly discuss the chief methods of treatment that have been employed for the treatment of psoas abscess. These are as follow :—

The expectant or non-operative, repeated aspiration, free incision and drainage, tapping with a large trocar and cannula, washing out and injection of iodoform emulsion, free incision, followed by scraping with a flushing curette with or without drainage, and incision, thorough cleansing of the cavity and sewing up.

As I have already pointed out to you, treatment by rest alone may result in spontaneous cure. Previous to the development of antiseptic and aseptic methods this was the treatment that surgeons were led to adopt owing to the disastrous results which usually followed upon operative interference from secondary infection of the cavity through the admission of micro-organisms. At the present day, it is often wise to treat the patient by rest in the recumbent posture before resorting to operative measures, but it is unwise to wait once an abscess has fairly developed, lest it should extend beyond the limits of the abdomen.

Of operative measures, aspiration alone cannot be recommended, as frequently the needle of the aspirator becomes blocked with caseous matter and in any case the cavity cannot be thoroughly emptied. Treatment by free incision and drainage under the antiseptic system was introduced by Lister and often gave excellent results, but the treatment by drainage is open to one very grave objection, viz., the very great danger that exists of infection taking place even with due precautions, owing to the possible infection or displacement of dressings. The treatment by tapping with a large trocar and cannula, followed by thorough washing out with hot saline solution and the injection of iodoform emulsion has many advocates. It is, however, open to the objection that it does not completely evacuate the contents and that there is some risk of iodoform toxæmia ; whilst even its most ardent supporters admit that a cure is only occasionally obtained in this way by one tapping, and that more commonly the fluid re-collects and the same process has to be repeated two or three times. The method of curetting with a sharp spoon is one that I cannot approve of, it injures the tissues unnecessarily, starts bleeding into the cavity and opens up fresh fields for infection with tubercular material if spinal disease be still active.

The treatment I have employed in the present case is one that I have successfully used on several occasions and I cannot recall a single instance of failure since adopting it several years ago. I find that it is practically identical with the method advocated by Mr. Tubby (Green's "Encyclopædia Medica"), who recommends the introduction of a solution of menthol, 1 drachm dissolved in 1 oz. of alcohol, which is added to and mixed with one pint of glycerine. Personally, I have every confidence in a solution of iodine as an application after the cavity has been thoroughly cleansed. It must be remembered, however, that if necrosis is still going on in the vertebræ, a re-collection of pus is almost certain to take place, no matter what method of treatment is adopted. The points which I wish particularly to emphasise are : (1) free incision or incisions in suitable situations ; (2) thorough cleansing of every part of the cavity ; (3) arrest of hæmorrhage ; (4) the application of iodine or some reliable non-irritating disinfectant to the interior of the sac ; (5) the obliteration of the cavity by pressure ; (6) thorough closure of the wound by sutures ; and (7) the observance of the strictest aseptic precautions.

In some instances it may be necessary to make two or more incisions, such as one in the loin one in the iliac region, and one below Poupart's ligament. The one large ilio-lumbar incision which I have described is usually sufficient to enable the operator to reach all parts of the abscess cavity and gain access to the diseased part of the vertebral column.

The general treatment of the patient must be attended to in all cases. This will consist of the administration of such remedies as iodide of iron and cod-liver oil, free and nutritious diet and open air treatment.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by J. Odery Symes, M.D., London, Bacteriologist and Assistant Physician to the Bristol General Hospital, on "Chronic Rheumatism and Rheumatoid Arthritis."*

(*a*) The patient returned home June 9th.

ORIGINAL PAPERS.

PULSE TENSION: ITS CLINICAL SIGNIFICANCE.*

By H. W. SYERS, M.A., M.D.CANTAB.,
Physician to the Great Northern Central Hospital.

(Concluded from our last No.)

PART II.

I will now consider in the light of the history of a few cases some of the abnormalities ascertained to exist by means of the Riva-Rocci instrument.

In Addison's disease, the pulse tension is extremely low; in a case I had in the wards some months ago it fell to 35 mm., being the lowest I have yet seen. The case was a very advanced one, and the patient died about a fortnight after admission. It is worthy of mention that the administration of adrenalin had not the slightest influence in raising the blood pressure.

Low tension of pulse may be almost the one feature which suggests the possibility of a case being one of Addison's disease. We are occasionally confronted with youthful patients whose one complaint is of increasing feebleness on exertion. On examination, extreme feebleness of pulse may be recognised. Such patients are pale and may be extremely anæmic, but there is no evidence of pigmentation. The possibility of the case being one of Addison's disease should certainly be borne in mind, for not seldom in this malady the essential feature, weakness of circulation, may considerably antedate the onset of morbid pigmentation.

In pernicious anæmia the pulse tension is also much below the normal. In a case under my care not long ago it was 87 mm. In this case the heart was diagnosed as fattily degenerate, and the diagnosis was confirmed *post mortem*.

The pulse tension in so-called functional albuminuria is invariably low according to my experience. Last summer I had a case of this description under observation for some weeks. The patient was a boy of 14, whom I first saw in the out-patient room. There was a considerable quantity of albumen, but no evidence of renal disease could be made out. Next time there was no albumen. Some days it would be present, others absent, and he was then sent into the hospital for closer observation. The blood pressure, kindly and most carefully taken by Dr. Clarke, senior house physician, varied from a maximum of 100 mm. to a minimum of 75 mm. But it is important to notice that no relationship whatever could be traced below lowness of pressure at a given moment and the occurrence of albuminuria.

Thus there was no albumen at 100 mm., but it was also absent at 80 mm.; it was repeatedly present at 95 mm., and again absent at 75 mm. Hence it seems clear that the presence of this form of albuminuria is not dependent exclusively upon blood pressure.

In cases of renal disease still in the acute stage, with hæmaturia, such being chiefly children, frequent observations on the arterial tension are very desirable; in this way we can ascertain whether the condition is becoming chronic, and the prognosis will thus greatly depend upon the result of these observations. I constantly employ the Riva-Rocci instrument in such cases, and with the greatest benefit.

The following case illustrates the by no means unusual combination of shortness of breath and œdema due to failing renal heart and high tension. The patient was a woman, æt. 54, who for some months had suffered from increasing shortness of breath, and œdema of the lower extremities. The pulse tension registered 165 mm., the action of the heart was cantering and very irregular. In spite of continued rest in bed the lower extremities remained very œdematous. A certain degree of relief was obtained by the use of iodide of potash and liquor trinitrini, but the dyspnœa was increased and the general symptoms were aggravated by the employment of digitalis. This case clearly shows that, in spite of loss of compensation, the pulse tension may remain high; it continued more or less unduly elevated up to the time of the patient's death.

There can be no doubt that chronic heart disease, and more especially that which is combined with arterio-sclerotic change, often tends to the production of the emphysematous condition. This is the reason why, in such cases, it is often quite impossible to determine the area of superficial cardiac dulness, and it is worthy of notice that other sclerotic lesions may be present in cases of this form of degeneration of arteries.

Not long ago I saw a woman whose pulse tension was much increased and who was also suffering from fibrosis of the left lung, leading to much contraction of that side of the chest. There was also albuminuria and other evidence pointing to the presence of granular kidney. There can be no doubt that in this case there was a general fibrosis of organs, and the process which had attacked the arteries was merely the manifestation of a general morbid tendency.

It is important in all cases of arterial degeneration to be on the look-out for other evidence of cirrhotic alteration in the organs, for I am convinced that the change is not seldom a general one and may be regarded as the premature appearance of that degeneration which in extreme old age is found to affect every organ and tissue of the body—a change which transforms the whole structure into a connective tissue.

Another instance is one of arterio-sclerosis in a soldier, as the result of hardship in the South African war. He was admitted for chronic dysentery. The Riva-Rocci instrument gave a reading of 168 mm., and a faint systolic murmur was audible at the heart apex and the aortic base, extending to the right clavicle. In a case such as this the Riva-Rocci instrument is of the utmost value. It is often difficult to estimate the precise significance of a systolic murmur at apex and base in middle-aged persons, with no antecedent rheumatic history. But when the Riva-Rocci reading is found to be abnormally high, there can be no question that the murmurs are due to atheroma of the aortic and mitral valves respectively, and hence appropriate treatment should be at once inaugurated, in order to avoid the onset of the disastrous consequences of chronic high arterial tension.

In cases such as this it must never be forgotten, in forming a prognosis, that the conditions affecting the root of the aorta which give rise to a systolic murmur are just those which may lead to a stenosis of the coronary artery. Thus the mere fact of a systolic basic murmur being present, and which is due to degenerative aortic disease, may be an indication of the not remote and sudden occurrence of angina pectoris by which life may be brought to an end.

Hence it follows that the presence of atheroma of the ascending aortic arch should never be regarded otherwise than as a serious lesion.

A middle aged man with renal disease became suddenly unconscious, and it was, of course, of the first importance to determine the cause of the seizure. In a case such as this, the blood pressure may be a reliable aid in the diagnosis, should the pressure be high (in this instance it was 200 mm.), it may be confidently affirmed that cerebral hæmorrhage is the lesion actually present, and so it was found in this case. A timely venesection may be of great service in such a condition.

On the other hand a girl, æt. 16, suffering from malignant endocarditis with mitral systolic murmur, was the subject of a seizure in which consciousness was completely lost for many hours and in which also more or less generalised convulsions were present. The Riva-Rocci instrument showed a pressure of 87 to 90 mm., in other words arterial tension was greatly reduced. At the *post mortem* examination it was found that the lesion was embolic arterial plugging, with consecutive softening of the right frontal globe.

These cases, both of recent occurrence in the wards of this hospital, show the value of pulse tension observations in the diagnosis of conditions in which

unconsciousness is a prominent symptom. I need scarcely point out that the treatment applicable to the case of cerebral hæmorrhage would be wholly inadmissible in a case of embolism or thrombosis in which the symptoms are very similar, so much so, indeed, that, without the aid of the sphygmomanometer it might be impossible to differentiate them.

A case such as the following presents itself: A man of 70 complains of shortness of breath, especially on exertion, and a troublesome cough. On examination, he is found to be the subject of marked chronic bronchitis and emphysema, and the heart is dilated, its action being irregular.

The radial arteries are sclerosed in the highest degree, but in spite of the feeble action of the heart, the blood pressure registers 155 mm. Albuminuria is present, and it is clear that the correct diagnosis is that of granular kidney, with extreme arterial degeneration and failing compensation on the part of the heart.

How is this case to be treated? If digitalis is ordered it is obvious that the already greatly increased peripheral resistance will be still further augmented, and thus an increased strain will be thrown on the labouring heart. Further, digitalis at the best, can only whip up the failing organ to increased efforts, of which it is probable it is already more or less incapable through mural changes. It seems tolerably clear that digitalis, at all events given by itself, is ruled out in a case such as this. Far more reasonable would seem to be that form of treatment which, by reducing the peripheral resistance, should enable the feeble heart to forward the blood with greater ease through the peripheral vascular system. In other words, the employment of the vaso-dilator drugs would appear to be clearly indicated.

Of these iodide of sodium would probably be the first made use of, and with satisfactory results. It must not be forgotten that in cases such as these, the progress of arterial sclerosis is far advanced, the elasticity of the arterial wall is a thing of the past, and the great thickening of the same offers a mechanical impediment to the passage of the blood. Hence it follows that the dilating mechanism is altogether and hopelessly out of gear. It is well in such cases to test the effect of liquor trinitrini in one or two minim doses, for the greater the fall in the arterial pressure, within reasonable limits, the more favourable is the prospect of treatment.

I am convinced that the routine administration of digitalis and of other drugs of the same nature in this very commonly met with class of case does nothing but harm. On the other hand, much relief to the distressing symptoms may result from the administration of small doses of liquor trinitrini, of tetranitrate of erythol, or of iodide of sodium. It is another question as to the advisability of ordering such drugs as these merely for the purpose of reducing tension and keeping it permanently low. That it is possible to do this I entertain no manner of doubt, but as to the wisdom of the procedure I am more sceptical. Each case, it seems to me, must be treated on its merits. When very high tension is present, and still more when disastrous evidence of its existence has been furnished by cerebral hæmorrhage, then, indeed, there can be no hesitation as to the expediency of reducing pressure in as permanent a manner as possible. I may instance the case of a woman, æt. 64, who came to the hospital with the very high tension of 250 mm. on the Riva-Rocci instrument, she had a week or two previously awakened in the morning with inability to speak clearly. The case was obviously one of amnesia due to slight hæmorragic effusion probably beneath Broca's convolution. There was considerable degeneration of the radial artery. This patient was put on 10 grain doses of iodide of potash with the result that in a few days the arterial tension fell to 220 mm. A 2 minim dose of liquor trinitrini brought down the tension nearly 20 points in less than half an hour. She was afterwards treated with small doses of liquor trinitrini and finally left the hospital with a tension of 175 mm. only. I repeat that, under such circumstances, there can be no question as to the desirability of doing all in one's power to reduce arterial tension in order to avoid further hæmorrhage, or other complication. The case is widely different when merely increase of blood pressure is observed, without any definite symptom such as dyspnœa or other uræmic manifestation. It is quite certain that the increased tension is an effort of nature to avoid further troubles, and as such I think in the majority of cases that it is best to confine our efforts to the hygienic and dietetic management of the condition, eschewing the use of vaso-dilator drugs, or at all events confining this mode of treatment to the employment of the iodides.

I have already referred to the patient suffering from chronic dysentery, but who was also found to be the subject of atheroma and high arterial tension. The dysenteric symptoms were not at all acute, but he complained from time to time of somewhat severe pain in the upper abdomen.

When seen on one occasion the customary pain was unusually severe and continuous; it was, too, located higher than usual, being chiefly felt across the epigastrium. The pulse tension was found to be 180 mm., and, as the pain did not appear to be directly the result of the intestinal disorder, it was thought that perchance the increase of arterial tension might be to some extent, at least, responsible for the symptoms.

Two minims of liquor trinitrini were given; in about a quarter of an hour the pulse tension had fallen from 160 mm. to 125 mm. or 35 mm. relief was obtained almost immediately. Forty minutes after the administration of the drug the tension was still 125 mm., the patient was then entirely free from pain, though he had been suffering acutely for many hours previously. There can be little doubt that in this case the determination of the pulse tension led to the adoption of appropriate treatment, for it seems clear that the distress in this instance was the result, not of chronic dysentery, but of a pseudo anginal attack associated with arterial degeneration and high tension.

It is of importance to notice the extent of the fall of pressure in this case. A drop of 35 mm. in a few minutes proves that there must still be a considerable degree of elasticity as regards the arterial walls; in other words, these are not the seat of an extremely marked degenerative process.

In another instance, one in which the peripheral vessels were absolutely rigid and pipe-like, the pulse tension being 190, the administration of two minims of liquor trinitrini was followed by no definite fall.

In the case of a man, æt. 50, suffering from chronic nephritis in its most advanced stage and manifesting marked renal dyspnœa, a two minim dose of liquor trinitrini reduced arterial pressure from 196 mm. to 185 mm., in about 5 minutes. Half-an-hour afterwards the pressure was still 185 mm. Two days afterwards the same dose produced no definite fall, and a negative result ensued also at the next trial.

I may incidentally remark that, after venesection to 20 ozs. the blood pressure was as high as ever next day, varying from 190 mm. to 200 mm., and slightly over. This was in spite of his having taken three minims of liquor trinitrini three times a day. In this case there was extreme degeneration and rigidity of the arterial wall, and hence probably but little structure remained on which the drug could act. On the other hand, in a man of 42, suffering from hepatic cirrhosis and ascites, a pulse tension of 160 mm. was present. Iodide of potash in 5 grain doses was ordered three times a day, and in a few days the tension had fallen to 140 mm.

There has been, and is, considerable difference of opinion as concerns the power of the iodides of potash and soda to reduce arterial tension, but the examples already given will, I think, leave no doubt in the mind of the unprejudiced observer as to the ability of the iodides to perform this pressure-reducing function. As a final example I may cite the case of a patient

suffering from early G. P. I., with arterial degeneration, in whom the tension on admission was 170 mm.: After some days' treatment with iodide of potash, pressure fell to 138 mm.; after further treatment, in a fortnight's time the pressure fell to 120 m.m., and kept at this level.

No doubt the rest in bed and careful dieting of hospital patients suffering from high arterial tension have something to do with the fall of pressure; but if treatment with the iodides be withheld for a week or so after the admission of the patient, the results will undoubtedly lead to the conviction that the drug treatment is the main factor in the lowering of arterial tension which almost invariably results.

Arterial sclerosis is an incurable malady; it is much better to accept this fact and to cease to look for remedies which will cure a condition incapable of being amended. All we can do is to palliate the affection and endeavour to arrest its progress. The chief points to attend to in order to attain these ends are to carefully regulate the hygienic conditions under which the patient lives, to cut off all indulgence in tobacco and stimulants, so far as may be possible, to ensure the absence of worry and anxiety, and to see that the patient uses plenty of drinking water. The latter is an important point and I am convinced that much of the gouty and uric acid tendency observed at the present day is due to this omission.

The dietary in cases of arterial degeneration and in high arterial tension is a matter of extreme importance. Yet it is the greatest possible mistake to suppose that these patients must be fed entirely by rule. Far too much attention is devoted at the present time to the feeding of patients on what may be termed physiological principles, the attempt to reduce the diet and so arrange it that such and such a number of units, and no more, of nitrogen, &c., are consumed. These and like efforts are foredoomed to failure, for they do not take into account that most potent influence affecting the human economy—idiosyncrasy.

Spa treatment is often very efficacious. Harrogate is a very suitable spa for the treatment of cases of morbid arterial tension, and both the baths and waters are of much use in dealing with the lesion and its attendant maladies. Doubtless the regulated life at health resorts is a powerful agency in bringing about the favourable results which certainly ensue, but it is impossible not to attribute active therapeutic effects to such potent waters as the saline sulphur springs of Harrogate and other similar spas. Be this as it may, it is certain that many gouty, overfed patients with increased arterial tension derive the greatest benefit from treatment at Harrogate and other mineral springs.

There are certain abnormal cardiac conditions which are not infrequently found to accompany states of high arterial tension and degeneration. Hypertrophy of the left ventricle is the rule, but a dilated state of the cavities is not at all unusual, and, as I have already pointed out, the onset of very marked and pronounced dilatation does not by any means imply the necessary occurrence of low tension. On the contrary, in such circumstances the tension may continue very high, 180 mm. and higher.

That degeneration of the heart muscle should accompany the morbid elevation of tension is only what might be expected; it is by no means uncommonly found, and in my experience it is chiefly fibrous degeneration which is met with. It is particularly well-marked in the papillary muscles of the left ventricle.

As regards fatty degeneration, I am bound to say that it is far more often diagnosed than found in the *post mortem* room. No doubt it is most difficult, indeed, wholly impossible in most cases, to be certain of the presence of this form of heart decay, and there can be no doubt, as pointed out by the late Dr. Balfour, that mere heart debility is constantly interpreted as being due to the presence of fatty change in the cardiac muscle. It is occasionally a matter of surprise that a condition of extreme degeneration of the myocardium, together probably with the coronary arteries and vascular system generally, has been consistent with prolonged and even active life. At *post mortem* examinations of patients dying from causes other than heart disease it is not uncommon to find the latter organ in an advanced stage of degeneration. It seems difficult to explain the absence of heart symptoms unless it be assumed that the pericardium acts as a supporting agent holding together the weakened cardiac muscle. Scarcely enough attention would seem to have been devoted to the aid furnished by the pericardium in maintaining the integrity of a degenerate and enfeebled heart muscle. A highly instructive instance occurred in the case of a man of advanced years who died suddenly in the street. In this case most extensive fibrous degeneration of the left ventricle was present, and in one point the ventricular wall had yielded; the resulting aneurysm of the heart contained tolerably firm clot. Rupture of the aneurysm appeared to be imminent, and was apparently prevented only by firm pericardial adhesions over the site of the lesion.

There can I think be no doubt that, in not a few cases of fatty or fibroid degeneration of the heart muscle, a catastrophe is only prevented by the tightly investing and tough pericardium. The time has surely come in which the estimation of the pulse tension in accurate terms must be as necessary a part of a thorough medical examination as is the use of the stethoscope, the ophthalmoscope, or the clinical thermometer. It has been my endeavour to show how indispensable is the employment of the sphygmomanometer as a means of clinical examination, and that in a very large proportion of patients a record of pulse tension is a necessity both as regards prognosis and treatment. I feel certain that in no long time the ordinary clinical equipment will be completed by the addition of this instrument, and the result can only be in every respect thoroughly satisfactory.

PERFORATED GASTRIC AND DUODENAL ULCERS:

SOME OBSERVATIONS BASED ON A PERSONAL EXPERIENCE OF FORTY-SIX CASES OPERATED UPON.*

By ALEXANDER MILES, M.D., F.R.C.S.E.,

Lecturer on Surgery in the School of Medicine, Royal Colleges of Edinburgh; Assistant Surgeon, Edinburgh Royal Infirmary.

MR. MILES pointed out that if duodenal were included along with gastric ulcers, perforation was a comparatively frequent occurrence in males. In his series of thirty-six gastric and ten duodenal ulcers, twenty of the patients were males and twenty-six females. It followed from this that in a case of perforation the diagnosis as between appendix mischief and gastric (or duodenal) ulcer could not be allowed to depend to any extent on the patient's sex. As to the question of age in relation to prognosis, his patients had varied between 15½ and 55½ years, and an analysis of the figures showed that on the whole the prospect of recovery was better in young persons. A previous history of dyspepsia or ulcer was very common, and he had not infrequently noted that for some time before perforation occurred there had been comparative freedom from stomach symptoms. On the other hand, in not a few instances premonitory symptoms of perforation had taken place in the occurrence of exacerbations of the dyspepsia, particularly in the occurrence of pain and tenderness. Like Mr. Caird, he had been struck by the comparative rarity of a history of vomiting blood or of blood in the stools. He had analysed

(*) Paper read before the Edinburgh Medico-Chirurgical Society, July 4th, 1906.

his cases with the view of determining whether work, muscular efforts, trauma, or the ingestion of food had been the cause exciting perforation, and the general results were inconclusive; for while in one or two instances rupture of the ulcer had followed efforts, injury, strain, or a hearty meal, in most cases it was impossible to trace any definite connection between such occurrence and perforation. In eight cases the accident had taken place when the stomach was full, in thirteen, when it was partially empty, and in seven when it was presumably quite empty. The site of perforated ulcer was usually on the anterior wall near the pyloric end of the stomach, and towards the lesser curvature. Of gastric ulcers, thirty-three were anterior, three posterior; of duodenal, nine were anterior, and one posterior. In this respect his statistics corresponded pretty closely with the figures in F. Brunner's collected data. He had only one case of multiple perforation in his series. As might be expected, the largest perforations were those attended by the highest mortality. In considering the clinical features it was important to distinguish clearly between two sets of symptoms—those due to the perforation and those due to ensuing peritonitis. There was often a period of latency after the acute onset, and during this time the diagnosis was sometimes reconsidered and time lost in consequence. A knowledge of the fact that the pain, &c., which followed perforation might temporarily abate was therefore important. In these circumstances the patient and his friends might demur to the need for operation, until chance of recovery was considerably lessened. Pain, occurring suddenly, was of great diagnostic value. In two cases he had seen it referred to the back, but he had never noticed the pain under the left clavicle referred to by some authors. The seat of the pain was, in his experience, an important guide to the site of ulcer, and it was his practice to make his incision where the tenderness and pain were greatest. The pain of a perforated appendix might, however, exactly simulate that of gastric ulcer. Vomiting was not common when perforation occurred. Abdominal rigidity was extremely constant, and set in early; it was often associated with retraction of the abdomen. Percussion gave little help, and he did not place much reliance on variations in the liver dulness. After twenty-four hours it was of no assistance, either positively or negatively. Sometimes an effusion into the lesser sac gave rise to a dull area in the umbilical region; this, of course, was due to rupture of a posterior gastric ulcer. After the initial shock came a period of reaction and temporary improvement, and, for the reasons given above, it was essential to estimate this at its proper value. It was his impression that opium, besides masking the symptoms, exercised a notably unfavourable influence on the prospect of recovery.

As regards operation, he preferred a vertical incision over the most tender area, splitting the fibres of the rectus. On opening the abdomen gas and fluid escaped, but he had very seldom been able to recognise food particles in the fluid. The perforation was found by carefully removing flakes of lymph from the stomach wall. It was seldom, if ever, necessary to open the stomach in order to discover the rupture, and in general he deprecated any procedure of this kind, or gastro-enterostomy, in a patient who was collapsed from a perforation. The ulcer should be closed by a Czerny-Lembert suture and covered by an omental graft. He could not recommend that the ulcer should be excised. In some cases it might be necessary to perform pyloroplasty in order to prevent the likelihood of a future stenosis, but he did not care to perform gastro-enterostomy purely as a matter of precaution. The peritoneal cavity should be purified by irrigation, and drained by a supra-pubic tube. Local drainage he no longer employed, but raised the head of the bed so that fluid might gravitate into the pelvis. In the after treatment rectal salines and intravenous transfusion were required; he thought that it was perfectly safe to give a little fluid by the mouth after twenty-four hours had elapsed. Among the complications which had supervened in his series of cases were temporary gastric fistula, pneumonia, parotitis, phlebitis, bronchitis, and pelvic abscess. The chief factor in the prognosis is early operation; the condition of the stomach in regard to food at the time of rupture did not seem to have any influence, nor did the site of the perforation, nor the presence or absence of initial vomiting. In statistical form his results were as follows:—Operation within 12 hours of perforation: 14 recoveries, 3 deaths (26·3 per cent.); between 12 and 24 hours, 5 recoveries, 4 deaths (44·4 per cent.); between 24 and 36 hours, 3 recoveries, 3 deaths (50 per cent.); later than 36 hours, 1 recovery, 11 deaths (91·7 per cent.).

THE PROGRESS OF MEDICAL SCIENCE.

Graduation Address delivered on Tuesday, July 17th, 1906.

By JOHN GRAY M'KENDRICK, M.D., F.R.C.P., F.R.S.

Professor of Physiology in the University of Glasgow.

AFTER a few words of encouragement and advice to the graduates who were qualified and about to start in life on their varied careers in the profession, Professor M'Kendrick remarked that this address might also be considered his valedictory pronouncement before quitting the position he had held in the university for thirty years.

He then said: The next consideration I desire to lay before you is that medicine and surgery have both made remarkable progress during the last thirty years. You are all familiar with this fact. I need not enlarge on the wonderful progress made by so-called preventive medicine, by which the mortality from fevers and other infective diseases has been enormously reduced, more especially in our great towns. Nor need I do more than allude to aseptic surgery, by which thousands of lives are saved annually and the surgeon is able to perform with success many operations that were at one time deemed impossible. Gynæcology also has become a well-defined and most important branch of surgery, and by its methods lives are saved and existence to thousands made endurable. Nor can we forget that during the last thirty years the science of bacteriology has assumed such dimensions and is of such importance as to affect all departments of scientific medicine. Such progress has been made in all branches of the healing art that possibly some of you may feel discouraged, and you may think that little will be left for you to do. But you could not make a greater mistake. Marvellous

as has been the progress of the last thirty or forty years, it appears to me that we are on the road to great discoveries that may, as regards some details of practice, revolutionise the medical art.

Ideas precede discoveries in the onward march of science. The secrets of nature are not revealed at haphazard. Sometimes one with merely an inquisitive mind discovers a new phenomenon, apparently almost by chance; but the best work is done by the thinker, who meditates over phenomena with which he is familiar, and who invents a working hypothesis to explain the facts. Then he appeals to observation and experiment. The observations and experiments are then not at haphazard. The investigator knows what to look for, and he knows the kind of experiment that must be tried. Thus great general principles are established. It seems to me that we have in our day striking examples of this process of human thought. New ideas are everywhere in the air.

Physiology, pathology, and pharmacology are the hand-maidens of medicine. Practical medicine is no doubt an art, not a science, but it is based on knowledge derived from the three sciences I have mentioned. In these days it seems to me that these three branches of human activity are becoming more and more closely connected, and they are fertile in new ideas, ideas that must influence not only our conceptions of disease, but also our modes of treatment. It is now recognised that there are gradations both in health and disease. Probably a state of perfect health in any individual is rare; there are ups and downs; there are as it were different planes of health. Even in a person supposed to be in perfect health there may be morbid activity in some part of the body, some disease or other in its very earliest stages. One organ may not be performing its functions efficiently, and all the organs suffer more or less with it. It is becoming more and more clear that each organ may have more than one function, and that if one organ is the seat of disease, other organs may, within limits, act vicariously for it. We also see that morbid changes have a beginning, and if we could only detect them at this stage we might be able to employ therapeutic measures that would avert the morbid changes, or at all events modify their progress.

We also see that the body has numerous protective arrangements for defending itself against enemies, such as micro-organisms or poisonous substances generated even by itself. This is an idea only dimly perceived by our forefathers. The acidity of the gastric juice, the portal circulation, the abundance of adenoid tissue crowded with leucocytes in some of the so-called blood glands and in the alimentary tract, the influence of internal secretions, are all examples of what we may term a protective mechanism. The old physicians wrote much about a *vis medicatrix naturæ*. They had a glimmering of the truth. There is no *vis*, there is no principle that thus acts, but there is a tendency on the part of every tissue to resist attack, and if altered in a morbid direction, to revert to the condition that is normal. In your future work you will recognise these ideas, and they will help you in your practice.

It is instructive to observe how one idea leads on to another. Leucocytes were detected in the blood even by the early microscopists, but it is only in recent days that their importance has been suspected. First, their power of amœboid movement was observed, then their tendency to migrate in inflammatory conditions, and then the phenomena of phagocytosis, by which they are capable of devouring foreign micro-organisms. At the same time the life history of micro-organisms was studied. Ere long it was discovered that in many cases the micro-organism might not be injurious to the body *per se*, but that it produced a poisonous substance, a toxin. The next important step was taken when it was found that the toxin, in some mysterious way, produced an antitoxin, which neutralised the poisonous action of the toxin. This led to the formulation of the theory of Ehrlich, which has been singularly fruitful in the way of suggesting research. By the cultivation of antitoxins in serum, valuable remedial agents can now be used in the treatment of acute diseases caused primarily by micro-organisms. Nor is this the end of the wonderful story. It is found, as you are aware, that in serum there may be present bodies—chemical substances—no doubt derived from the tissues themselves, which have anti-bacterial powers. Little is yet known of the true nature of these so-called opsonins, but we have a method by which their power may be measured, and the opsonic index of the blood as a whole, or of the blood of different organs, may be determined. Here is another remarkable protective measure that may be taken advantage of in therapeutics. Whether the opsonins act by stimulating phagocytic action, or whether they so injure the infective micro-organisms as to lower their vitality, and thus make them an easy prey to the phagocytes, is not yet determined. All this has led to theories of immunisation and to measures of immunisation. It seems to me not improbable that we are entering on a new field of serum-therapeutics which may be of the greatest value. In many cases, no doubt, we will be beaten in our efforts, and the surgeon will be called in to remove, or lop off, or relieve from pressure, or give rest to ulcerated parts, but I cannot help thinking that in the future there will be less for him to do in this direction than in the past.

Another idea that is taking possession of the medical mind is that by therapeutic measures, while we cannot cure the disease, we can help the body to carry on its functions, not certainly on the high level of perfect health, but on a lower level of comparative comfort and efficiency. Physicians do not invariably attempt to treat actively a new set of symptoms that may make their appearance in a chronic case. They are afraid to do harm when they cannot see clearly that they can do good.

There is only one other idea I wish to refer to. You must have often been struck with the sad ravages of disease as revealed in the *post-mortem* room—the condition of the heart and kidneys, for example, being apparently incompatible with life. The wonder you felt was not that the patient died of the disease, but that he lived so long with organs that presented such morbid changes. When one sees a case like this, there is a tendency to be sceptical as to the use of drugs. But the condition was not of yesterday. Changes must have been going on for years, and yet the individual may have lived to a fairly old age and

even been active in the discharge of daily duty. Now, no remedies can work miracles. They cannot materially alter the condition of a diseased heart or of degenerated kidneys. And yet, if we recognise the idea that the body as a whole has wonderful compensatory arrangements and adjustments, by which life may be beneficently prolonged, we can do much by therapeutic means to assist nature. I frankly confess that as I have become older the crude scepticism of early years as to therapeutic measures has given place to a recognition of how much may be done to help by the judicious use of our *materia medica*.

It is evident, then, ladies and gentlemen, that there is still much for you to do in the active treatment of disease. Keep up your knowledge of physiology, pathology, and pharmacology. Link them together and you will find that one will illuminate and help the other. Study, for example, such a problem as that of helping a weak heart by the use of digitalis. You will find this problem full of instruction, and it will be a good test of your physiological knowledge. Do not practise by rule of thumb. Scrutinize each case that comes before you *per se*. Examinine it with the physiological and the pathological eye, and not through the distorting medium of a text-book, full of descriptions of "typical" cases. Then use your remedies wisely and well, with as full an acquaintance as you can command of their pharmacology. Take care not to do harm, and always have a definite idea as to how you hope to do good by the use of a particular remedy. This will give you satisfaction with your work.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

OPERATION FOR UNDESCENDED TESTICLE.—MR. BOYCE BARROW operated on a child, æt. about 5, who had been brought to the hospital on account of an undescended testicle. The testicle was lying in the left inguinal canal, where it was freely movable, but could not be protruded through the external abdominal ring. At the operation Mr. Barrow cut down on the inguinal canal which he laid freely open in the usual way; next pulling on the testicle with the fingers he opened the reflected portion of the peritoneum, and then with very great care divided the peritoneum investing the cord, which latter was made taut and brought into evidence by traction on the testicle, and thus light bands of tissue became successively recognisable. It became evident from the gradual elongation of the cord, as these bands were divided, that they constituted the chief cause of the imperfect descent of the testicle. The finger was then thrust into the scrotum and the way prepared for the testicle, which could now be carried to the bottom of the scrotum without difficulty, even to a lower level than the testicle of the right side. Its fixation in this position was effected by stitching the testicle to the subcutaneous tissue of the lower part of the scrotum, without, however, penetrating the skin (so that there should be no communication with the air in this situation). The retraction was also provided against by stitching the cord, as it passed out of the canal, to the pillars of the external abdominal ring. The inguinal canal was then perfectly closed and the wound stitched up. Mr. Barrow said that the advantages of this method were that the cord was secured in the canal by the stitches at the external abdominal ring, so that any tension on the testicle in the scrotum was obviated. He also laid stress on the importance of not penetrating the skin when stitching the testicle to the subcutaneous tissue of the lower part of the scrotum as through neglect of this precaution the air would be admitted and this would necessitate an antiseptic dressing in this position, which would tend to press the testicle upwards, whereas the object aimed at was to push the organ down by the pressure of the dressing on the inguinal canal. It was his experience, he remarked, that by the perfect division of the peritoneum the testicle could be got quite satisfactorily down in a very large number of cases, and it was, he thought, a distinct advantage for the patient not to be hampered and pained after the operation by any apparatus having for its object traction on the testicle and cord. He suggested that traction by an apparatus might possibly contribute to the atrophy of the testicle which sometimes results after the organ had been replaced in the scrotum. He considered that any necessity for an apparatus was done away with by (1) stitching the testicle to the bottom of the scrotum, and (2) stitching the cord to the pillars of the ring. He pointed out that great care has to be taken in dividing the delicate bands of tissue investing the cord, so as to avoid wounding either the vessels or the vas deferens (there was scarcely any vessel requiring ligature in the present case). The chief precaution in doing this was to carefully examine and make taut each band before dividing it. So far as his experience went in watching these cases afterwards, he said the permanent condition after this operation was satisfactory, there being but little tendency for the testicle to retract; besides, its nutrition could not be much impaired, as he had found the organ to grow fairly well after operation.

CANCER HOSPITAL.

SCIRRHUS OF BREAST.—MR. BOWREMAN JESSETT operated on a married woman, æt. 51, who had been admitted a fortnight before. She had noticed retraction of the left nipple twelve months ago. There had been no pain, but a lump had gradually developed in the breast. On admission a hard mass was found occupying the breast at the lower internal edge, the nipple was drawn in and the gland somewhat fixed to the muscle beneath. There was no ulceration of the skin. The glands in the axilla were enlarged; there was apparently no infection of the supra-clavicular glands. The patient's sister had died of cancer of the breast. Mr. Jessett removed the breast by a rectangular flap extending from the acromion process along the border of the great pectoral muscle to practically the ensiform cartilage. The flaps were reflected, the skin being carefully dissected off on either side. Next the breast was freely removed, care being taken to dissect off the fascia and integuments of the pectoral muscle. The glands in the axilla were also excised and the whole armpit cleared out, the vessels and nerves being freely exposed. It was found on deep examination that the glands were apparently affected above the clavicle, so Mr. Jessett made a rectangular flap above the clavicle and dissected down to the subclavian vessels and sheath of the carotid; he found a number of small glands which were enlarged, and these he removed. The wound was then closed without difficulty, and the patient returned to bed. Mr. Jessett said that instructions were given to tie the left arm up to the head of the bed, so as to keep the limb at right angles to the body. Mr. Jessett insisted on the importance of freely removing the fascia and integuments over the pectoralis major in all cases of scirrhus of the breast;

but he did not think it necessary to cut away the muscle itself unless the disease was found to have penetrated into its substance, as the lymphatics of the breast travel by the integuments and fascia to the axillary glands and not through the muscles. He said it was very important to examine at the time of operation the glands above the clavicle, and if they were found to be at all enlarged he considered a free dissection of the anterior triangle of the neck should be made and the glands removed, as by doing this serious trouble in the future was often averted. He pointed out the desirability after operation of tying up the patient's arm to the head of the bed so as to keep it at right angles, for by adopting this plan free motion of the limb was ensured in the future.

TRANSACTIONS OF SOCIETIES.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

LAST MEETING OF THE SESSION HELD FRIDAY, JULY 13, 1906.

Mr. PRIESTLY SMITH, F.R.C.S., President, in the Chair.

MR. A. R. BRAILEY read a paper on

CONGENITAL DISTICHIASIS.

and gave a clinical description of a case, together with the result obtained by making a microscopical examination of a small portion of the lid. The chief point of interest was the fact that the Meibomian glands were apparently completely absent, and their place was taken by hair follicles. He then gave a description of four other cases seen in the Clinic of Professor Fuchs, in Vienna. Those were the only cases seen there during a period of twenty years, and showed how rare this deformity was. He then described a case reported by Kuhnt. He drew attention to the distinction which should be recognised between trichiasis and distichiasis, and urged the advisability of limiting the latter to the congenital cases. He gave a list of other cases which had been reported.

Dr. C. H. USHER (Aberdeen) read a paper on

THE CHOROID AT THE MACULAR REGION.

He drew attention to the fact that in sections of the eyes of Albinos examined by Mr. Nettleship, and shown at a meeting of the society in November last, that pigment was present in the choroid, but limited to the yellow spot region.

He had since examined eleven normally pigmented eyes, and had found (1) a deeper pigmentation of the retinal epithelium at the yellow spot region, and an increased thickness of this layer; (2) a marked increase of the pigmentation of the choroid, and (3) an increase in the thickness of the choroid.

From the above observations it might be expected that if pigment were present at all in an Albino's eye, it would be found in the macular region.

Dr. Usher also read a paper on a case of

UNILATERAL WHITE EYELASHES AND TUFTS OF HAIR.

The patient was a girl, æt. 3, whose eyelashes on the left side were quite white, and she also had two tufts of white hair on the left side of her head. There was nothing else abnormal in the mother or child, and the pregnancy was normal in every way. The condition was first noticed about the third day after birth. All the eyelashes on the right side were light brown in colour, so also was the greater part of the hair of the head. The family history was carefully investigated, and although there were some Albinos in the family, yet no other member seems to have had this peculiar condition.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 15th, 1906.

PROSTATITIS IN THE MIDDLE-AGED.

WHAT is meant by prostatitis in middle life, in persons between forty and fifty years of age? How can the precocious apparition of prostatic troubles in such young men be explained, since it is generally admitted that hypertrophy of the prostate is an affection of advanced life?

The theory given by Dr. Le Fur of hypertrophy of the prostate explains the existence of the affection in middle life.

Before the French Association of Urology, that author showed that hypertrophy of the gland was only the terminal period of chronic prostatitis; intra-glandular lesions at first, then periglandular and interstitial; no foreign element was necessary to the development of the glandular lesions to give a sufficient pathogenic explanation of hypertrophy of the prostate; age only comes in as an indispensable factor, permitting the lesions of the gland to develop and establish themselves definitely. The long latent period preceding the malady is very variable; relatively short in middle life, it lasts generally much longer in other cases, when the symptoms begin to appear between sixty to seventy years of age.

This conception of the inflammatory nature of hypertrophy of the prostate had already been entertained by a certain number of authors as Griffiths, Reliquet, Guépin, &c., who believed that this affection was a frequent consequence of gonorrhœal prostatitis. However, a large number of patients suffering from hypertrophy of the prostates had never contracted gonorrhœa.

According to Le Fur, hypertrophy of the prostate can result from all inflammations of the gland, due to a general affection, infectious malady or an intestinal affection, especially to muco-membranous entero-colitis.

Hypertrophy of the gland can be also produced by simple modification or troubles of the secretion or excretion of the prostatic glands. It was to this hypersecretion, hyposecretion, or retention of the products of secretion, that Le Fur gave the term of aseptic prostatitis or prostatitis of physiological order. As these cases arise chiefly from sexual abuse (prolonged, modified or too frequent coitus and masturbation).

In middle life the lesion of the prostate differs from those observed at a much later period. Instead of the hard sclerous form, a gland, soft and vascular, with hypersecretive and notable hypertrophy. It is this variety that is the most amenable to treatment.

One or two cases in point: Patient, æt. 40, had several times gonorrhœa with symptoms of subacute prostatitis, frequent attacks of congestion, during which the patient did not wholly empty his bladder. Prostate soft, large, double-lobed.

Massage of the prostate produced an abundant flow of prostatic liquid and milky urine. The massage was continued and the urethra was largely dilated, while a solution of nitrate of silver was instilled into the posterior urethra.

At the end of a month the patient was able to empty his bladder completely, and the cure was complete.

Another patient, æt. 38, had several times gonorrhœa. suffered from nocturnal incontinence, constipation. Prostate large and soft. After two months' treatment as in the first case the patient was definitely cured.

From the above it is evident that the best treatment in prostatic affections of middle life consists in massage, large dilatation of the urethra, instillation and irrigation of the canal.

GERMANY.

Berlin, July 15th, 1906.

AT the Medical Society, Hr. Wolff related the following case: A woman who had aborted four times in three years, found herself pregnant again, and again aborted. The speaker found in the outer wall of the cervix uteri two sharp points and discovered that they were the two tips of a hair-pin. He managed to extract them after cutting off the points. The patient confessed that she had introduced a hair-pin with the convex end foremost, into the cervical canal for the purpose of procuring an abortion. She made a good recovery.

Hr. Hirschberg advocated the use of the magnet for extraction of the hair-pin in similar cases.

Hr. Oppenheim reported

TWO SUCCESSFUL OPERATIONS FOR TUMOUR OF THE SPINAL CORD.

The cases showed the great value from the point of view of treatment of the exact localisation of tumours. The first case was that of a woman, æt. 33 when first seen, who in November, 1904, came to the poliklinik complaining of pain between the shoulders and the neck. In October there had been pain and a feeling of weakness in the left arm. Examination showed narrowing of the left pupil, some paresis of the left upper extremity, especially weakness of the biceps and the muscles of the hands and fingers. Slight diminution of electrical excitability, paræsthesia in the arm, and deadening of sensibility; the left leg dragged on walking with slight spastic paresis, no atrophy or vasomotor disturbance. There was no evidence of syphilis. On the right, sensibility was markedly diminished as far as the second rib. The course of the disease pointed to a new growth at the level of the sixth and seventh cervical vertebræ of meningeal origin. There was also tenderness on pressure.

The patient was sent to the surgical klinik for operation. The Rontgen rays showed no changes. The patient could not bring herself to decide for an operation and left the hospital.

In September she returned, as the condition had got very much worse. There was now complete paralysis of the lower extremities, especially pronounced on the left side, great reflex irritability, and spastic phenomena on the right; there was also paralysis of the sphincters. The compression of the spinal cord had become complete. The pain, moreover, had now ceased, a symptom not rarely observed in this disease.

The operation was performed on September 23rd by Burckhardt. The tumour was found in the exact situation predicted and removed; it was intradural, and was reached after removing the sixth and seventh vertebral arches. The cord was compressed almost to a ribbon at the site of the tumour. It was a fibro-sarcoma. Improvement soon took place. In four days slight movement returned in the legs. Early in October, the sphincter function returned. Some attempts were made at walking. The patient now walked quite well; only slight traces of Brown-Séquard's paralysis remained. The right arm acted quite well; the muscles of the left were atrophic.

The second case was that of a man, æt. 49, who came to the poliklinik in July, 1905. He first had signs of paræsthesia in the legs in the autumn of 1904; then pain followed in the back and abdomen, and, after that, weakness and stiffness in the legs, weakness of the bladder, and impotence. On admission, there were found to be weakness in the legs with stiffness of the muscles and exaggeration of the knee-jerks. Ataxic movements on both sides, disturbance of sensibility, and particularly of the sense of temperature, which on the right side from the umbilicus to the seventh rib was quite extinguished, whilst the symptom was less pronounced on the left. On movement, there was pain in the middle of the dorsal region; here there was also tenderness on pressure over the fifth dorsal vertebra. The diagnosis lay between a new growth in the cord or paralysis of the lateral columns. The speaker could not, therefore, advise operation, but first of all treatment by massage, &c. At first there was improvement, but it did not continue; the disturbance of movement and sensibility rather increased, so that the speaker felt certain the case was one of new growth. An operation was performed by Burckhardt on March 22nd. The tumour was found at the expected spot; but for its extirpation three arches had to be removed. It was a fibro-sarcoma. It could only be removed piecemeal through being so crumbly. Improvement was noticed even on the second day; then, however, a short period of exacerbation took place with rise of temperature and incontinence. After six days, however, steady improvement set in. At present the most noticeable feature was some ataxic movement. It was hoped that as the operation was so recent (two months) the remaining signs of paralysis would also disappear.

AUSTRIA.

Vienna, July 15th, 1906.

SPINAL NEOPLASM.

AT the Gesellschaft Schreiber exhibited a patient whom he had previously shown to the Society two years ago. According to the history of the patient the illness commenced about Christmas, 1902, with great pain in the left shoulder, which was treated for weeks as rheumatism. In February, 1903, or two months later, the lower part of the cervical vertebræ became very tender, and the neck began to increase in thickness. Movement gave great pain and the suffering still increased with neuralgic severity till head and arm could not be moved. A surgeon was consulted and spondylitis diagnosed. Shortly afterwards a large fluctuating tumour appeared. Morphia and other sedatives were given to alleviate pain. Paræsthesia began to appear in the left arm, which soon developed in tonic spasms of the whole body, permanent paresis and atrophy of the left arm. These paralytic conditions increased till the left leg was similarly implicated. This went on increasing till the neck measured 44 centimetres in June, although it was only 36 centimetres in February, two months after the disease commenced. The patient was taken into Schnitzler's clinic where she lay four weeks, awaiting a favourable opportunity for operation, as the diagnosis was now confirmed that a neoplasm was present. During this delay the tumour took on a hardening appearance and soon became as hard as bone. In the autumn of 1903 the neuralgic pains subsided, the tumour became less in size and the patient began to move about greatly improved in general strength, and nervous system normal. The case was presented at a meeting two years ago, May, 1904, with a Röntgen photograph. On the posterior surface of the lower cervical vertebræ a large bony tumour about the size of a man's fist with its base lying on the spinous process and arch of the vertebræ while the canal and body were perfectly free. The tumour seemed to contain within itself portions of bony structure enclosed in capsules.

The tumour was allowed to remain undisturbed without therapy or operation of any kind whatever, as the health seemed good and all danger of paralysis had disappeared; while the circumference of the neck descended from 44 centimetres to 37·8. The last Röntgen examination was made in April of present year, when nothing but the capsule of the tumour seemed to be left. After four years' observation with very little treatment we are able to declare the tumour neither caries nor malignant, and only a mixture of fibrous and cellular tissue with calcareous deposit.

ANEURYSM.

Frisch showed a preparation taken from the ulnar artery of a patient he showed to the Society on April 27th, when a little discussion arose on the propriety of extirpating the tumour as the man was æt. 64, and the diagnosis sclerosis.

Notwithstanding the division of opinion Frisch operated, and has proved to his opponents that no arterial sclerosis exists and that the cause of the

aneurysm is what he affirmed from the first, to repeated or chronic series of injuries to the artery.

SEMMELWEIS MEMORIAL.

An appeal is now made to the Vienna practitioners to subscribe to the erection of a statue to the memory of one who has done so much for medicine and mankind. He is represented as preceding Lister in antiseptics and particularly demonstrating the etiology and prophylaxis of child-bed fevers. There is a statue of Semmelweis at Buda Pest already, but Vienna thinks it a duty to erect another in the town in which he laboured.

HOSPITAL ACCOMMODATION.

Vogler made an interpellation in the House of Parliament on the want of accommodation existing in Vienna at the present time for infectious diseases.

The case of a labourer was given who went round all the Vienna hospitals seeking for admission, but was refused. At last he resolved on theft to force his admission, and stole a pair of boots from a shop window. He was apprehended and secured his object. On recovering from the disease he was again taken before the justices and punished with three days' imprisonment. The case is causing a good deal of public and private incrimination.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

NOTIFICATION OF INFECTIOUS DISEASES IN EDINBURGH.—For many years after the adoption of a system of notifying infectious diseases in Edinburgh, measles was included among the diseases notifiable. About four years ago, however, on the adoption of the General Act, instead of the private Act previously in force, notification of measles was dropped. The Public Health Committee of the Town Council have recently, by a majority, carried a resolution that the first case of measles occurring in a family should be made notifiable, and the proposal will come before the Town Council at an early date. Councillor Robertson, who is a medical man in active practice, has also moved that the notification of phthisis be made compulsory. This resolution has been remitted to a sub-committee for consideration and report. The notification of measles was suspended because it was found, as in other towns, that it had no effect in checking epidemics. The object of notifying first cases seems chiefly to be that it will allow the authorities to discover when the disease is prevalent, and guide them in taking general measures to check its spread. From the nature of the infection there is, of course, no hope that isolation of individual cases, once the disease has declared itself, can prevent extension of infection to anything like the same extent as in the case of most other diseases.

BALDORAN ASYLUM FOR IMBECILE CHILDREN.—The directors have marked the completion of the fiftieth year of the existence of this institution by issuing a review of the rise and growth of the asylum. The original building was designed both for imbeciles and orphans, the idea being that when the former reached a certain stage of cure association with normal children would be beneficial. In the light of present knowledge it is no surprise to learn that this idea was not justified by events, it being found that the imbecile exercised a deleterious influence on the normal children. At the time of its opening in 1855, the asylum received patients under a sheriff's warrant as in the case of adult lunatics. Now, of course, this clumsy procedure has passed away, and private pupils are admitted as their guardians desire as easily as any children can be sent to any educational institution. In 1855 there were 5 girls and 2 boys resident, and the work of the institution fairly commenced. In 1858 the asylum came under the newly created Lunacy Board, and among other results was that more attention began to be paid to physical improvement and less to ordinary teaching. This year closed with 17 pupils, the numbers seeking enrolment on the books of the institution, until in 1879, when the buildings were greatly extended, the licence was increased to 70 pupils, and this year, with additional new buildings the institution is licensed for 160 children, of whom already 154 are resident. In the half century of its existence 676 children have passed through the institution, and it was never so full as now. In the concluding pages of the report, Dr. Greig, the medical superintendent, describes the present work of the asylum. Those who take an interest in the question of the education of the feeble minded will find in the Baldoran Jubilee Report much that is suggestive.

EDINBURGH ROYAL INFIRMARY.—At their last meeting the managers appointed Dr. R. W. Philip, one of the ordinary physicians, vice Dr. Smart, whose tenure of office will shortly expire; Dr. Norman Walker was also appointed physician for diseases of the skin, in place of Dr. W. Allan Jamieson. The managers have decided to decline the offer of the Admiralty to give them the use of the Royal Navy sick quarters at Butlaw as a sanatorium. The buildings are some distance from the railway station and are considered otherwise as unsuitable.

LETTERS TO THE EDITOR.

THE CHRISTIAN SCIENCE TRIAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Clement H. Sers is quite correct in the suggestion in the last paragraph of his excellent letter in your issue of July 11th; but as much confusion seems to prevail as to the law of responsibility in the case of such sects as the Peculiar People and Christian Scientists, perhaps you will allow me to state broadly how the matter stands. Parents and guardians having charge of children are bound to obtain medical aid when called for. If they fail in this duty, and if it be proved that death is accelerated or caused by their neglect, they are liable to a charge of manslaughter. In all such cases a coroner would so instruct his jury. Persons in charge of adults not able to look after themselves—for example, idiots, imbeciles, or lunatics—would, under similar circumstances, have the same responsibilities. In the case of other adults there exists, of course, no law to compel anyone to avail himself of medical science or to call in a medical man; and there is no legal obligation upon friends or relations or attendants to insist upon the summoning of medical aid. The recent Christian Science case was complicated by the fact that one of the attendants was a qualified medical man. His own evidence, and much corroborative evidence, however, went to show that he had given up medical science in favour of Christian Science; that he was called in by the deceased man expressly because he was a Christian Scientist; and that it was thoroughly understood and agreed upon between them, that the case was to be treated not according to medical science, but according to the ritual or rites of the religious sect in question. Although such a course might seem to differ in some cases very little from deliberate suicide, there appears nothing in the law to make anyone concerned liable to a criminal charge. The Judge at the late trial clearly laid this down. The same judge had within the previous few weeks passed a sentence of hard labour upon a member of the Peculiar People—a father whose children had died through lack of medical treatment—and there can be no doubt the Judge, one of the hardest-headed on the Bench, was fully master of the law which he was called upon to interpret.

I am, Sir, yours truly,

July 11th, 1906. COMMON LAW.

"SHODDY LEARNED TITLES" AND THE "VALUE OF AMBULANCE WORK."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to your leaderettes in your issues of June 27th last, *re* "Shoddy Learned Titles" and "Value of Ambulance Work."

Apparently you are not aware of the full facts of the case, inasmuch as a local practitioner wrote some "Notes on First Aid," and on the front appeared his name followed by his medical titles, L.R.C.P., L.R.C.S. L.F.P.S., and then followed certain Indian appointments, and then in capital letters, M.B.,M.A., F.R.G.S. This constitutes the basis of the complaint of the local medical men in this city, which led to the case being laid before the branch of the B. M. Association. As your leaderette shows such an interest in the matter, I have pleasure in informing you of the above points.

I am, Sir, yours truly,

ETHICS.

Bradford, July 13th, 1906.

THE NEWSPAPER PRESS AND QUACKERY.

WE are allowed to print the following excerpts from a private letter from a distinguished F.R.S., and Professor in the Biological Department of one of our English Universities :—

"I was very much interested in your articles on the subject of quackery, and I quite agree with your views on that subject, and also on the painful degeneration of the *Times*. I think the *Times* has not nearly so much influence now as it had formerly. In the North, very few people seem to read it or pay attention to its opinions. . . . The great mischief and injury done by quackery, however, chiefly affect people who never see the *Times*—I mean the lower middle and working classes. We have hundreds of quacks in —— doing a thriving business, and inflicting untold misery on the people of these classes. These people have much more faith in advertisements than in leading articles. I believe that the only thing to advocate is much more stringent legislation. It ought to be a penal offence for an unqualified man to advertise for patients suffering from consumption, cancer, &c. By co-operation with workers among the poor, a great deal of startling evidence could be found concerning the injuries inflicted by quacks. . . . I think that the best, if not the only opportunity that the medical profession has of appealing to the intelligence of the layman is that afforded by the October addresses at the medical schools, which are widely read by the general public. How rarely do they deal with the subject of quackery."

SPECIAL ARTICLES.

THE NEW PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

MR. HENRY MORRIS, Consulting Surgeon to the Middlesex Hospital, has been elected by the Council, the president of the Royal College of Surgeons for the ensuing year. We congratulate Mr. Morris upon the high honour to which he has attained. Everyone will admit that he is a distinguished representative of the art of surgery in this country, and in gaining that which no doubt has been his ambition, we are sure that Mr. Morris will worthily fulfil the duties of the post, and amply justify the confidence which has been placed in him by his colleagues. Mr. Morris has worked well and laboriously for the college in the past as chairman of the Finance Committee of the Council, his elevation, therefore, to the presidency has doubtless come partly out of regard for his previous services, and in recognition of his fitness for the post. There is no gainsaying the fact that a man of good business parts is a *sine qua non* for the presidency of the college.

By virtue of his office he is frequently called upon to represent the college at public functions, social and otherwise, and it goes without saying that a good deal is always expected of him who has been adorned with the Blue Riband of surgical science in this country. There is, however, another aspect of the Presidential office which, it appears to us, claims somewhat serious attention, and that is the absence of any regular method on the part of the college of returning the hospitality which it receives through its representative. The president, by virtue of his office, is frequently invited to attend public dinners; that is to say, the college is entertained through its president, but the president cannot officially reciprocate the hospitality which he receives. A new order of things might, with advantage be inaugurated in this regard, and the council might arrange to give two, or perhaps, three, annual dinners to which might be invited the leading men of the sister professions and others from whom the college had received hospitality. In following out this suggestion the Council would be doing nothing more than that which has been the rule adopted by the Benchers of the various Inns of Court. However, it might be argued that the College of Surgeons is not a social club, but an institution devoted to science. That, of course, must be admitted; nevertheless the point must also be conceded that not even a scientific institution constituted as the College of Surgeons is can really afford to ignore the amenities of social life as existent in the present day. We believe that it would be to the interests of the College generally, and to the advancement of the surgical profession, were the policy to be inaugurated to which attention is here drawn.

SIR CHRISTOPHER NIXON, BART., M.D., F.R.C.P.I.

Physician to the Mater Misericordiæ Hospital, Dublin.

WE have already referred to the honour conferred on Sir Christopher Nixon, and through him to the medical profession in Ireland, by the awarding to him of a Baronetcy on the recent occasion of the celebration of his Majesty's birthday. Sir Christopher has also been honoured by being the recipient of the Honorary Diploma of L.A.H. from the Apothecaries' Company of Ireland. On this occasion, the Deputy Governor of the Hall, who introduced Sir Christopher, said he has filled every position to which his colleagues could elect him. He is Dean of the Medical School of the Catholic University—the most flourishing, indeed, we believe that we are correct in saying that it holds the unique position of being the only Medical School in Ireland which has an ever-increasing number of students passing through its portals. How much the remarkable success of this school is due to its Dean can be imagined. Sir Christopher Nixon is also a past

President of the Royal College of Physicians, and he still represents the Royal University of Ireland on the General Medical Council, the supreme governing body of our profession. He is Senior Physician in the Mater Misericordiæ Hospital, where his cliniques have always been of surpassing success and popularity. Her Majesty, our late beloved and ever-regretted Queen, was pleased to create him a Knight Bachelor, and to-day all English-speaking people read of the distinction conferred upon him by our gracious Sovereign King Edward VII. This honour can scarcely be more pleasing to its recipient than it is delightful to the medical profession in Ireland.

REVIEWS OF BOOKS.

HAIG ON THE URIC ACID PROBLEM (*a*).

JUDGING from the rapidity with which new editions of Dr. Haig's works issue from the Press, his now well-known views in relation to uric acid must have many followers both in the profession and amongst the general public. It is to the public that the present volume is addressed, and it says much for the decadence of the race that it should be necessary to issue a second edition within two years of the appearance of the first. Not that we wish by the use of the word decadence to cast any slur on the book or on the theories that it embodies, but to comment on the fact that so many of the general public are such close students of their often trivial symptoms as to be ready to procure, and we presume read, and possibly even follow the advice contained within it.

The last edition of Dr. Haig's larger work on the same subject received a lengthy review in our columns some two years ago. In it we dealt in some detail with his theories, and so it is unnecessary to repeat the opinions therein expressed, opinions we may say which have undergone no change since then. We need. therefore, only again point out that one of his fundamental assumptions, namely; that uric acid is always manufactured in the body in a definite proportion to the amount of urea manufactured, is untrue, and that in accordance therewith much of his argument at once falls to the ground. We may also say that Dr. Haig argues too much from the particular to the general, and that although some individuals possibly exist who, constituted like himself, find it desirable to restrict their diet to milk and cheese, it is absurd to argue therefrom that the whole human race, the majority of which happily is in excellent health, should do likewise. Even the possibility of extending one's life beyond the usual span, and prolonging one's days as an emaciated hypochondriac to a hundred years or more would, we are glad to think, hardly be a sufficient inducement to the average individual to make him sacrifice his briefer and happier life and more virile diet for the food of a confirmed invalid. An individual who feels ill if he eats an ordinary meal is obviously an invalid, and to such Dr. Haig should address himself and not to the world in general. Perhaps, indeed, we should be far more moral if we followed his precepts, but the extra morality would be bought with the loss of our position as a nation, and in these days when underfeeding and physical degeneration are regarded as so closely allied, we feel indeed that Dr. Haig must be courageous to so insist upon his views.

While making the above criticisms, we must in fairness add that the book itself is fascinating, and we can well understand how convincing it must appear to the uninformed, uncritical and neurasthenic layman. Perhaps its fascination suggests the advertisements we are so familiar with and which are worded so as to include all symptoms as the ones the remedy vaunted is beneficial for, or possibly it lies in the evident conviction of the author of the truth of his statements. The latter possibility we believe to be the true one, and while disagreeing with the author, we must at the same time congratulate him on the way in which he defends and maintains his opinions.

(*a*) "Uric Acid. An Epitome of the Subject." By Alexander Haig, F.R.C.P., Physician to the Metropolitan Hospital. Second Edition. London: J. and A. Churchill. 1906.

SHAW-MACKENZIE ON THE TREATMENT OF CANCER. (*a*)

THE fact that this work should have quickly passed into a third edition is sufficient testimony to the value of the facts and conclusions brought forward by the author. There is a charm, as well as an attraction, about this book, inasmuch as it deals with many hitherto but little-known physiological processes and applies them to clinical investigation. Thus it opens up a new field of science, apart from the special subject with which it deals, and within a small compass brings many an interesting fact before the general reader, which, under ordinary circumstances, he would never be likely to come across. How many practising physicians and surgeons, for example, ever heard of trypsin before the author brought it under the notice of the profession and proved its therapeutic value, besides showing its action upon glycosen. Furthermore, in this new edition, we are introduced to another animal ferment named Crepsin, the universal presence of which in animal tissue has been proved by the researches of Dr. H. M. Vernon. Cohnheim was the first to discover it, and the author draws attention to its probable value, in the treatment of cancer, as an adjunct to trypsin, inasmuch as experimental inquiry has demonstrated that the succus entericus, "crepsin," acts as a stimulant upon the pancreatic function, and so aids in the secretion of the proteolytic ferment of the pancreas. Here, then, is another problem which the work of the author has presented to the profession, namely, to what degree does the action of crepsin control or modify the cell growth in cancer when administered in combination with trypsin, and whether it has any influence in rendering the action of trypsin more effectual in such cases. Time only, and repeated observation can, of course, determine this point; meanwhile, it is just possible that trypsin alone may be indicated in some cases, and crepsin alone in others, in order to obtain the best results by this treatment. Thus it must be evident that only those who especially lay themselves out carefully to study the problems of this new therapeutic application of the animal ferments to the treatment of cancer, as laid down by the author, can hope to realise the expectations which he foreshadows as possible. Rome, as we are accustomed to be told, was not built in a day, neither can the exceedingly complex problem of the therapeutical treatment of malignant disease, be conceived, elaborated and perfected within the short compass of, say, a few months; and yet the results so far of the trypsin treatment, in this regard, have, as proved by the author, been so uniformly encouraging as to raise the best hopes that the arrest and cure of cancer is now within a measurable distance of accomplishment. We have, therefore, every confidence in highly recommending this work to the profession and urging its careful perusal.

LUNN'S PHILOSOPHY OF VOICE. (*b*)

THE success which this work has already attained has induced the author to revise it and to add much entirely new matter. The writer has gone to the song-birds for his fundamental teaching, as they give us correct examples of voice production from which we can learn much. In considering the infant voice the author points out that at the first cry of life we have clearness, volume, and intensity, three fundamental elements, and only continuity is wanting to transform such cry into musical sound. He warns

(*a*) "The Nature and Treatment of Cancer." By John A. Shaw-Mackenzie, M.D. Lond. Third Edition. Revised and Enlarged. London. Bailliere, Tindall and Cox. 1906. Price 2s 6d.

(*b*) "The Philosophy of Voice, showing the Right and Wrong Action of Voice in Speech and Song, with Laws for Self-Culture." By Charles Lunn. Pp. xix., 257. With 26 Illustrations. Tenth (Standard) Edition. Demy 8vo, 6s. net. London: Bailliere, Tindall and Cox.

against clavicular and so-called abdominal breathing. While singing we must never breathe through the nose. Singing under nasal inspiration is, he maintains, a physical impossibility. The chapter on the Natural Physics of Voice is excellent. Lunn maintains that it is a mistake to allow the singing voice to rest between the period of youth and adolescence. The break at puberty is only Nature taking advantage of a quickened growth of the parts to try and assert her original conditions from which she has been made to stray by speech and by vocal tuition.

The whole object of the work before us is to show the importance of keeping close to Nature. He harks back to the old school, and shows by examples that the compass of the bye-gone musical voice was greater than that of present day singers. This was owing to the better teaching and voice-production in these days. A chapter is devoted to stammering, which the author defines as a stoppage that cannot be moved. The mode of treatment suggested is based on sound principles, and is well worthy of consideration and trial. Looking at the book as a whole we are bound to admit that its teaching is sound. The subject is handled in a novel and fascinating manner, and the book differs very materially from all others of its class. It practically stands alone as the best treatise on voice production in the English language. There is not a dull page in the whole work, and it may be safely recommended to singers and public speakers as a trustworthy guide. Medical men will find much of interest within its pages, as patients often suffer from affections of the voice which cannot possibly be treated correctly, unless we have some general principles to guide us. The book is well printed, and tastefully bound and contains a number of beautiful illustrations. We warmly recommend it to those of our readers who may be interested in this important subject.

CARSON'S SURGICAL DIAGNOSIS. (*a*)

AFTER careful perusal we have come to the conclusion that this represents one of the best of a popular series of small books. Its 140 pages cover a great amount of ground, and cover the chief points of diagnosis in all the more important surgical conditions. Under the heading "Appendicitis," for instance, the main features that have to be weighed by the medical attendant are marshalled in a condensed analysis that is likely to be most useful to the student preparing for examination, or the busy practitioner wishing to refresh his memory upon the salient facts of the malady. What is said of appendicitis applies to the rest of the subjects treated by the author. We have also an excellent bird's-eye analysis of abscess of the liver, and the author has exercised the greatest care and judgment in every page of this little book, from the first chapter on "Methods of Examination," to the last on "Surgical Diseases of the Respiratory Organs," surprise being uppermost in the reviewer's mind after careful perusal, that it has been found possible to condense so much sound knowledge into such small compass.

COLBECK AND CHAPLIN'S PRESCRIBING. (*b*)

THIS is the second, enlarged and revised edition of a well-known and already much appreciated work. The subject is one of very great importance, especially in these days when we fear prescription writing is becoming a lost art. With this book before him, no student or practitioner need experience any difficulty in framing prescriptions for himself. The authors have made everything as simple as words can do, and have spared no pains in bringing home to their readers the importance of the subject from the point of view of everyday practice. The subject is treated largely from the clinical standpoint, and special attention has been directed to the means for correcting and disguising the taste of nauseous drugs. The various systems are dealt with *seriatim*, and prescriptions suited to the diseases of these systems are suggested and worked out in detail. This is a thoroughly practical guide, and no physician can afford to be without it unless he happens to be one of the old school. The profession owe a debt of gratitude to the authors of this valuable work for the pains they have taken to lay a sound foundation for the art of prescription writing which ought to be more generally practised by medical men. This volume has evidently a great future before it, and at present it certainly holds the field in its own particular subject.

BODILY DEFORMITIES. (*a*)

ON the death of the author of these lectures, Mr. Poland was requested to edit and revise the first volume. He has not attempted to alter the lectures from their characteristic style, but has merely omitted several obsolete tables and notes. The lectures—six in all—deal mainly with the etiological factors involved in the production of deformities of the human skeleton. These deformities the late Mr. Chance had exceptional opportunities of studying. In the lecture on "The Causes of Deformities Acting on the Embryo," the author has a good deal to say on the subject of maternal impressions, and cites a number of interesting examples. He is, however, a sceptic and entirely disbelieves in the asserted potency of such influences. He maintains that the parent can neither add to nor diminish the power of development which exists in the ovum immediately after impregnation, whereas there is no proof when once development has commenced the embryo is placed completely out of the mental influence of the parent.

In one of the lectures the author considers rachitis and scrofula as causes leading to acquired deformities. It is interesting to read that he regards all cases of rachitis as originating during uterine life—*i.e.*, "while development is going on, and while the basis of the osseous tissue is being laid down, and its constitution, as it were, given to it." He is, moreover, assured that this is a disease which is "unquestionably hereditary. The disease may remain dormant for a short time after birth, but as soon as the mother's milk is withdrawn then the disease resumes its activity and asserts, its powerful influence upon the skeleton generally, in the tissues of which the germ had been already implanted during uterine life." This view of rachitis is one which the author supports by table and data, but he overlooks entirely the effects which the disease has upon the tissues generally. His opinions, however, are interesting when considered in the light of more modern and advanced pædiatric knowledge.

Considering that fifty years have passed since these lectures were first delivered, we cannot wonder that much advance has been made in orthopædics; but still, nevertheless, Mr. Chance's observations remain to-day what they were then—a sound basis on which to rear a true physiological knowledge of this important branch of surgery. The present editor has endeavoured to embody in the form of very copious footnotes recent material bearing on the subjects under consideration, and he has added very considerably to the author's original drawings and notes of cases by others of his own. Mr. Poland hopes that these pages may afford some new material for reflection, and in this expectation we feel sure he will not be disappointed. We shall look forward with interest to the second volume, which we

(*a*) "On the Nature, Causes, Variety and Treatment of Bodily Deformities: In a Series of Lectures." Delivered at the City Orthopædic Hospital in the year 1852, and subsequently, by the late E. J. Chance, F.R.C.S., Surgeon to the City Orthopædic Hospital, &c. Edited by John Poland, F.R.C.S. Surgeon to the City Orthopædic Hospital, &c. Second Edition. In two volumes. Vol. I., 6s. net. London: Smith, Elder & Co.

trust will soon make its appearance. Meantime, the editor must feel considerable satisfaction on the issue of this work and the completion of part, at least, of what to him has been all through a labour involving no little time and trouble.

HEWLETT'S PATHOLOGY. (a)

This book is a good type of the modern school of pathology, which keeps in view the practical ends of its special branch of study. It does not profess to cover the whole field of knowledge, as known to the expert, but deals with the essentials of general and special pathology, such as are required by the medical student. The author in this way attempts a difficult task, which on the whole he has performed successfully within the compass of 525 pages of crown octavo size. The plan of the book renders it a convenient work of reference for the busy general practitioner. For instance, if he turns to any special point, such as malaria, gout, syphilis, or glanders, he will find all the salient points briefly noted. Of the *Spirochæta pallida*, it says that long spiral organisms of that organism have recently been detected in the lesions of syphilis, but that the specific micro-organism is unknown. A beautifully clear and concise account is given of the special pathology of the pancreas, an organ to which much attention has been devoted of late years. Although the condensation of the subject matter in this book has been insisted upon, it should be clearly understood that it is in no sense a cram book. An immense amount of special knowledge is presented by the author, who from his long experience as a lecturer at King's College, London, knows exactly what points the student should consider with the best advantage to himself. The book is certain to become popular among medical students, as in many ways it presents an ideal plan of conveying information useful for examinations.

GUIDE TO FINGER-PRINT IDENTIFICATION. (b)

THE recently-perfected method of identification by finger-prints is fascinating, if of no particular import to medical men. Its simplicity and its apparent trustworthiness combine to confer upon it a quite exceptional value in establishing unknown or contested identity. We are all branded by nature with an indelible and distinctively individual tracing which he who runs may read. The time may come when friends will exchange finger-prints as they now exchange photographs. A piquant interest is given to the subject by the photographic reproduction of finger-prints that have actually served to identify the criminal in a celebrated murder case.

The author claims to have been the first to call public attention to the method (*Nature*, October, 1880), and he is evidently very jealous lest the credit for having thought it out and introduced it should be wrested from him. This is, of course, very legitimate, but having formally registered his claim, he might well dispense with the elaborate documentary arguments which he brings to bear.

Mr. Faulds explains to us how the prints are obtained, how they should be dealt with for purposes of examination and classification, how they are generically classified, and the relative identificative importance of the special points observed; in short, with this book in hand and the disposition to work out the subject, every reader has it in his power to become an expert finger-print reader. To confer a medical interest on the subject, it remains to demonstrate that certain "whorls" "loops" and combinations thereof possess, at any rate, a pathological bearing. We should not be surprised to find that certain patterns are peculiar to light and dark-haired people respectively, that their diameter corresponds to height, or size of mouth, and that a measure of obliteration suffices to establish approximately the age of the "subject." It is obvious that this line of investigation is only in its infancy, and if clever women can base a forecast of our fate on a careful inspection of the comparatively coarse features of the palm, what may we not hope for from scientific study of the infinitely more delicate and complicated marking of finger-tips? *Verb. sap.*

OBITUARY.

JOHN HENRY EDDOWES, J.P., M.D., M.R.C.S., OF LOUGHBOROUGH.

THE death occurred on the 11th instant of Dr. John Henry Eddowes, J.P., at Loughborough. In the neighbourhood the deceased was one of the most popular of medical gentlemen. He was born at Loughborough, on October 13th, 1823, and was the son of the late Mr. John Henry Eddowes, surgeon. He was educated at the Loughborough Grammar School, and after one year at the Nottingham Hospital he went to St. Thomas's Hospital, London. In 1843, Mr. Eddowes obtained a prize for comparative anatomy; the following year he won the Chiseldon silver medal for clinical medical reports; and the following year secured the prize for clinical medicine. He became M.R.C.S. in 1846, and the same year L.S.A. In 1850 he took his degree of M.D., with honours at the University of Glasgow. In 1847 he joined his father in practice, and was later appointed honorary surgeon of the Loughborough Hospital.

Society for Relief of Widows and Orphans of Medical Men.

AT the Quarterly Court of the directors of this Society, held on Wednesday, last, July 11th, Dr. Blandford, President, in the chair, fourteen members were present. The death of Dr. John Clarke was reported, who was elected a member in 1847, and had been one of the vice-presidents since 1867. Four new members were elected. The sum of £1,358 10s. was voted for the half-yearly grants to the annuitants of the charity. Five letters had been received from widows of medical men since the last Court, asking for relief, and this had in each instance to be refused, owing to the fact that their husbands had not been members of the Society. Mr. Edward J. Blackett was re-elected secretary. The membership of the Society is open to any registered man, who at the time of his election is in practice within a radius of twenty miles from Charing Cross. Full particulars and application forms may be had from the Secretary at 11, Chandos Street, Cavendish Square, W. The next election is on October 10th, and names of intending candidates must be received on or before September 19.

The Caledonian Medical Society.

AT the twenty-sixth annual meeting of this Society, held last week at Stirling, under the presidency of Dr. W. A. Mackintosh, of Stirling, the report by the hon. secretary showed the membership to be 232, or double what it was ten years ago. Financially also the society was in a stronger position than ever it had been. Dr. A. Little, of Bradford, was appointed president for the ensuing year, and Dr. J. Keay, of Edinburgh, vice-president. Dr. John Dunlop, Bradford, and Dr. Cameron Blair, of Northern Nigeria, were elected to vacancies on the council. It was resolved to hold the next annual meeting in Bradford. Dr. Mackintosh then delivered his presidential address, and in the evening the annual dinner of the Society was held in the Golden Lion Hotel, Stirling.

BRITISH Medical Association visitors to Toronto will have an opportunity of visiting the Mushoka Lakes District by an excursion train, which is announced to leave Toronto, on Saturday, August 25th. Other most interesting trips to Lake Nipissing and the Temagami Region have also been organised.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England. The New President.

A QUARTERLY meeting of the Council of the College was held on Thursday last when Mr. Henry Morris, consulting surgeon to Middlesex Hospital, was elected President. Mr. Edmund Owen, surgeon to St. Mary's Hospital and Mr. Rickman J. Godlee, Surgeon to University College Hospital, were elected Vice-Presidents. The following appointments were also made for the ensuing collegiate year :—*Hunterian Professors* —Mr. Wm. Sampson Handley, M.S.Lond., F.R.C.S. ; Mr. J. W. Thompson Walker, M.B.Edin. ; F.R.C.S. ; Mr. J. Howell Evans, M.B.Oxon., F.R.C.S. ; Mr. William Wright, M.B.Vict., F.R.C.S., of Birmingham University and Owens College, Manchester ; Mr. Cecil F. Beadles, M.R.C.S., L.R.C.P.Lond., F.R.C.S. *Arris and Gale Lecturers*—Mr. J. Faulkner Dobson, M.S.Lond., F.R.C.S., of the School of Medicine, Leeds ; Dr. Bertram L. Abrahams, F.R.C.P. *Erasmus Wilson Lecturers*—Mr. Willmott H. Evans, F.R.C.S. ; Mr. Reginald C. Elmslie, M.S.Lond., F.R.C.S. ; Mr. Kenneth, W. Goadby, M.R.C.S., L.R.C.P.Lond. The following resolution moved by Mr. J. Ward Cousins and seconded by Mr. R. J. Godlee, was adopted: "That, in the opinion of the Royal College of Surgeons of England, it is essential for the efficient working of the Midwives Act that adequate provision be made to secure just remuneration for professional services rendered by medical men when called into attendance by midwives practising under the Act." A letter was received from the Secretary to the Faculty of Medicine of Harvard University thanking the College for presenting to the Faculty a collection of prints and engravings of physicians and surgeons. On the recommendation of the Museum Committee it was decided to print Vol. III. of the second edition of the Museum Catalogue of the Physiological Series of Comparative Anatomy.

Royal College of Surgeons, Ireland.

Prize List, Summer Session, 1906.—Barker Anatomical Prize, £31 10s.—P. G. M. Elvery. *Carmichael Scholarship*, £15—C. Greer. *Gold and Silver Medals in Operative Surgery*—Gold, D. Adams ; silver, R. M. Bronte. *Stoney Memorial Gold Medal in Anatomy*—G. S. Levis. *Practical Histology*—R. Adams, First Prize (£2) and Medal ; O. W. J. Wynne, Second Prize (£1) and Certificate. *Practical Chemistry*—J. J. Lyons and P. I. Wigeder (equal), First Prize (£2) and Medal. *Public Health and Forensic Medicine*—T. C. Boyd and C. T. Cullimore (equal), First Prize, (£2) and Medal. *Materia Medica*—J. J. Lyons, First Prize (£2) and Medal ; H. W. White, Second Prize (£1) and Certificate. *Biology*—H. D. Gasteen, First Prize (£2) and Medal ; J. S. Pegum, Second Prize (£1) and Certificate. The lectures of the Winter Session will commence on Monday, October 15th.

Barker Anatomical Prize for 1907.—A prize of £21 is offered for competition, and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The preparations entered must be placed in charge of the Curator on or before April 30th, 1907. The prize is offered for a dissection showing the viscera in relation with the abdominal surface of the diaphragm. The relations of the common bile duct, which should be seen opened up along its entire length, to be fully retained. Conditions under which the competition is to be carried out :—1. The preparations must be sent to the Curator of the Museum, Royal College of Surgeons, each being marked with a fictitious signature, and accompanied by a sealed envelope bearing outside the same signature, and containing within, (*a*) The full name of the competitor ; (*b*) A declaration to the effect that the work of the preparation has been carried out by himself. The printed form necessary for this declaration can be obtained on application to the Curator. 2. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster of Paris settings are not compulsory if the specimens can be better displayed and preserved by other means. 3. No prize will be awarded unless sufficient merit be shown, 70 per cent. of the total marks being the minimum. The following is the scale of marks : (*a*) For the merit of dissection, 60 ; (*b*) for excellence of setting, 20 ; (*c*) for originality, 20 ; total, 100. Those dissections for which prizes are awarded become the property of the college. 4. Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the cost of production as the Examiners deem fit. 5. The cost and risks of transport must be borne by the student. The College will not be responsible for any damage the preparations may sustain ; but those of unsuccessful competitors residing at a distance will be carefully re-packed and handed to the carriers for delivery at such address as may be specified by the student.—Arthur H. White, Curator of the Museum. *Extract from the will of the late Dr. Barker, formerly Curator of the Museum* :—"This Prize to be awarded by the Curator of the Royal College of Surgeons in Ireland for the time being, the President of the College, and the Professor of Anatomy of the University of Dublin."

Diphtheria in the Midlands.

A SERIOUS outbreak of diphtheria has occurred in the village of Fleckney, in Leicestershire, and is causing great alarm in the surrounding towns and villages. The epidemic has been prevalent for some months now, but recently the number of cases has increased to an alarming extent. Eighteen fresh cases have occurred in the last four days, and the inhabitants are in despair. Nearly half the houses in the village have been affected, and there have been several deaths.

Laryngological Society of London.

THE following have been elected Officers and Members of the Council for the ensuing session, 1906 7 : —*President*—J. B. Ball, M.D. *Vice-Presidents* — F. Willcocks, M.D., Charters J. Symonds, F.R.C.S., William Hill, M.D., and P. Watson-Williams, M.D. *Hon. Treasurer*—H. B. Robinson, F.R.C.S. *Hon. Librarian*—St. Clair Thomson, M.D. *Hon. Secretaries*—H. J. Davis, M.B., W. Jobson Horne, M.D. *Council*—Sir Felix Semon, K.C.V.O., M.D., Philip de Santi, F.R.C.S., J. Middlemass Hunt, M.B., S. Paget, F.R.C.S., and Attwood Thorne, M.B.

A Clean Bill of Health.

No case of notifiable disease has occurred in the district of Wadebridge, Cornwall, which has a population of 2,000, for two years. This speaks well both for the sanitary administration and for the healthiness of the district.

The Amalgamation of the London Medical Societies.

IN view of the present position of the negotiations between the Organisation Committee of the Scheme for the Amalgamation of the London Societies as it affects the Union of the Obstetrical and Gynæcological Societies, the Council of the latter Society has decided to summon a conference of its representatives with the Provincial Fellows. This conference will be held by kind permission of the Council of the Royal Botanical Society in the Museum, in the grounds of the Society in Regent's Park, on Thursday,

July 26th, at 4.30. Dr. Macnaughton-Jones has kindly arranged for refreshments for the Fellows in the grounds of the Society after the meeting.

A Serious Indian Medico-Legal Action.

RECENTLY a number of medical men, chiefly native practitioners, started a College of Physicians and Surgeons at Calcutta. The original and existing College of Calcutta have now entered a legal plaint in the High Court, charging the defendants with having wrongfully and illegally conspired to injure the said college in various ways; for having set up a bogus institution of the same name; alluring the students of the College, and also for having had recourse to diverse unfair means to lower the prestige of the college in the eyes of the public. A sum of Rs. 40,000 is claimed as damages by the College.

Diphtheria and Schools.

The Education Committee of the London County Council recommended that they should be authorised to refuse, during the presence of diphtheria in any district, re-admission to school of children excluded on account of diphtheria or sore throat until such children should have obtained a medical certificate of freedom from infection, based on a bacteriological examination. The recommendation was, after discussion, adopted.

AT a special meeting of Governors of the London City Orthopædic Hospital on July 10th, it was decided to agree to the amalgamation scheme that has so long been urged upon them by the Hospital Sunday and King Edward's Funds. The three hospitals, the Royal, the National, and the City Orthopædic will henceforth be merged in one institution.

PASS LISTS.

University of Birmingham.

THE following is a list of successful candidates in the Faculty of Medicine at the examinations in June, 1906.

Degree of Doctor of Medicine.—Thomas Webb Fowler, Robert Beatson Dennis Hird, Alfred Ernest Remmett Weaver.

Degree of Master of Surgery.—(*a*) Official, Frank Marsh; (*b*) Under ordinary regulations—Class I.—Alex Wathen Nuthall.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—(*a*) Past students of Birmingham Medical School.—Class II.—Frank Newstead Deakin, Charles Henry Maskew. (*b*) Under ordinary regulations—Class II.—Reginald Hudson Astbury, John Staines Austin, Arthur Cecil Hincks, Claude Johnson, Harold Bruce Jones, Walter Rowland Southall Roberts.

Fourth Examination for the Degrees of M.B., Ch.B.—Class I.—James Fenton, Arthur Addison Sanders, Francis Brett Young. Class II.—Edward James Boome, Henry Neville Crowe, Eric Thomas Gaunt, John Kennedy Gaunt, Philip James Mason, Nevill Coghill Penrose, Arthur John Smith, Rupert Wesley Thompson, Norman Valentine Williams.

Third Examination for the Degrees of M.B., Ch.B.—Part I.—Pathology and Bacteriology.—Class II.—John Adams, Charlotte Bailey, John Dale, George Henry Chavasse Mold, David Priestley Smith, Edward Vernon Whitby. Part II.—Materia Medica and Pharmacy.—Class I.—John Adams, John Dale, Harvey Atkins Evans, Edward Vernon Whitby. Class II.—Charlotte Bailey.

Second Examination for the Degrees of M.B., Ch.B. Class II.—Walter Charles Blackham, Norman Alexander Boswell, Harold Gordon Browning, Humphrey Francis Humphreys, Violet Maud McCready, Cranston Walker, Kenneth Douglas Wilkinson. Passed in part of the examination.—James Henry Bampton (anatomy and comparative anatomy), John Selwyn Edwards (anatomy and physiology), Carl Euclid Molino (anatomy and physiology), Ethel Annie Waldron (anatomy and physiology), Harold Arthur Whitcombe (anatomy and physiology), Henry Wilks (anatomy and comparative anatomy).

First Examination for the Degrees of M.B., Ch.B.—Class II.—Eric Walter Assinder, Oscar Madeley Holden, Elizabeth Stephens Impey, Lionel Gilbert Jordan, Ronald Douglas Nelson, Henry Richmond.

Degree of Bachelor of Dental Surgery.—Class I.—William Bowater.

Trinity College, Dublin.

THE following have passed the Intermediate Medical Examination—Part I.:—John L. Phibbs, Richard P. Hadden, Albert J. Stals, and Thomas A. Hughes, Passed on High Marks; Adams A. M'Connell, Herbert V. Stanley, Cecil P. Smyly and William A. R. Spong (equal), Duncan F. Hunter, Peter H. Lemass, Arthur H. Laird, John D. Kernan, George B. M'Hutchison and William N. Watson (equal), Richard J. Attridge and Eric J. Powell (equal) Charles G. S. Baronsfeather, Frederick R. Sayers, Harold T. Sugars. *Purser Medal in Institutes of Medicine*—Richard P. Hadden.

The following have passed the Final Medical Examination—Part II.—*Midwifery.*—Gustav W. Thompson (passed on High Marks), Edward Gibbon, Robert B. Jackson, Thomas L. de Courcy, Cecil T. Conyngham and Henry B. Leech (equal), Henry D. Woodroffe, George Dougan, Wilfred L. Hogan and Thomas B. W. MacQuaide (equal), Charles G. Sherlock and Theodore C. Somerville (equal), Francis W. H. Bigley and Thomas J Cobbe, (equal) John B. B. Whelan, Madeleine S. Baker, Albert J. T. M'Creery, James E. M'Farlane, Ernest C. Crawford and Joseph H. Elliott (equal).

University of Glasgow Final Professional Examination.

THE following candidates have passed the Fourth (Final) Professional Examination:—

For M.B., C.M.—Robert Stewart M'Kim, M.A.

For M.B., Ch.B.—James Montgomery Anderson, John Anderson, M.A., B.Sc., Thomas Barbour, M.A., B.Sc., George Duncan Morrison Beaton, Charles Burns, John Miller Hopkins Caldwell, William Rome Cammock, George Campbell, William Archibald Campbell, Henry Howard Christie, John Sawers Clark, M.A., James Coutts, Thomas Lawson Craig, Arthur Muir Crawford, James Richan Drever, M.A., Ernest Milne Eaton, William Gilbert, William Gilfillan, Arnold Harris Gray, Robert Neil Guthrie, Charles Francis Dyer Hammond, William Towers Hardie, Robert M'Cowan Hill, Alexander Hunter, Archibald Yuill Hutchison, John Keys, James Dunlop Kidd, William Hendrie Kirk, Alexander M'Call, Thomas M'Cririck, M.A., B.Sc., David Macdonald, James M'Farlane, John Robert M'Gilvray, William Anderson M'Kellar, William Ferguson Mackenzie, Norman Smith MacNaughtan, Alister Argyle Campbell M'Neill, Elizabeth Maud M'Vail, Andrew Alexander M'Whan, Florence Mann, William Hislop Manson, M.A., Robert Marshall, John Miller, William Miller, Peter Mitchell, M.A., Edith Oversby, James Hogg Paul, Agnes Picken, M.A., Alexander MacMillan Pollock, Thomas Hood Rankin, Vera Dagmar Reis, Frederick Gordon Robertson, William James Rutherfurd, William Hermann Sieger, William Smellie, Thomas Baillie Smith, James Stevenson, John Stevenson, Thomas Strain, David Laurence Tate, Charles Samson Thomson, George Haswell Wilson, James Wyper, John Young (Mount Vernon), Morris Youdelevitz Young.

The following passed with distinction in the subjects indicated:—

In (*a*) *Surgery and Clinical Surgery* (*b*) *Practice of Medicine and Clinical Medicine*—Robert Stewart M'Kim, M.A. (old regulations); Charles Samson Thomson. In (*a*) *Practice of Medicine and Clinical Medicine* (*b*) *Midwifery*—William Smellie. *In Surgery and Clinical Surgery*—James M'Farlane, Elizabeth Maud M'Vail, Peter Mitchell, M.A.; Agnes Picken, M.A., John Stevenson, John Young (Mount Vernon)., Morris Youdelevitz Young. *In Practice of Medicine and Clinical Medicine*—John Anderson, M.A., B.Sc., Arthur Muir Crawford, James Richan Drever, M.A., Arnold Harris Gray, William James Rutherfurd. *In Midwifery*—Andrew Alexander M'Whan, James Stevenson, George Haswell Wilson.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS.

ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Rise of Temperature from Suggestion in the Tuberculous.—Lorenz (*Beit. z. Klin. der Tuberk.*, Wurzburg 1906.) relates his experiences with a number of tuberculous patients who were given sham injections of tuberculin. His tables show an almost regular increase in temperature after a sham injection in 44 out of 200 persons tested. The excitement and the suggestion send the temperature up, although none of the supposed tuberculin was really injected. His experience suggests that it might be wise to test the influence of suggestion in this way before really injecting the tuberculin later. A rise of half a centigrade degree can be accepted as a positive reaction to the tuberculin. It should be computed from the temperature noted after the sham injection, allowing for the rise due to effects of suggestion. The sham injections were liable not only to send up the temperature, but also to affect the general health. It was noticed sometimes that those patients who had the most pronounced rise of temperature after a series of sham injections failed to show any rise when a genuine injection was given. Another fact noted was that the suggestive reaction was generally more pronounced when the organism was depressed from any cause, a slight cold or inflammatory process in a tooth or the like. D.

Reduction of Salt in Diet in Scarlet Fever.—Pater (*Presse Med.*, Paris, 1906) reports the results of salt starvation in 15 cases of scarlet fever. They demonstrate beyond question, he thinks, that this method of treating scarlet fever is absolutely simple and harmless, while it protects against complications, especially on the part of the kidneys. He found in his cases the course of the disease was shorter than usual, convalescence commencing earlier. If albuminuria was noted at first it subsided as salt was dispensed with. Dopter has also reported similarly favourable experiences, all tendency to nephritis being apparently averted. D.

Action of Iodine in Experimental Arterial Affection.—Koranyi (*Deut. Med. Woch*, Berlin, 1906) mentions experiments with iodine in arterial necrosis produced by adrenalin. Twenty-three rabbits were treated with adrenalin and 11 with subcutaneous administration of iodine at the same time. The results showed that the necrosis of the arteries which inevitably followed the injections of adrenalin could be prevented by simultaneous injection of iodine. He suggests that this observation may prove of therapeutic importance. D.

Epileptiform Seizures of Pleural Origin.—Roch (*Revue de Med.*, Paris, 1906) reviews 54 cases of convulsions suggesting epilepsy, in which the inciting cause was some affection involving the pleura. The pleurisy in some cases favoured the development of convulsions primarily due to other causes, but in others the pleurisy was evidently the sole inciting cause. The action is manifestly a reflex phenomenon. It was observed unmistakably in four well-defined cases. This assumption is also sustained by the cases on record of severe nervous disturbances in pleuritis, independent of operative trauma, such as coughing, hemiplegia, or sudden death. D.

Atropin and Strychnine combined a Remedy for Sea-Sickness.—Brig.-Gen. A. H. C. Girard (*Journ. Amer. Assoc.*, June 23rd, 1906) gives a summary of his investigations extending over several years in the treatment of sea-sickness. He states that in almost every instance a hypodermic injection of gr. 8-$\frac{1}{100}$ atropin sulph. with gr. 8-$\frac{1}{60}$ strych. sulph, is readily borne by adults and causes no disagreeable sensation. This may be taken at the commencement of a voyage, or when the sea commences to be rough, or at the advent of a storm causing nausea. This dose is at times not sufficient with persons refractory to the action of belladonna, and may have to be repeated twice at hourly intervals before incipient dryness of the throat gives warning that atropinism has been reached, when in every instance the symptoms of sea-sickness disappeared. As a rule one dose is sufficient for a whole voyage, apparently overcoming the disturbance until the voyagers acquired their "sea legs," but in a long trip with severe weather occasional doses are required to keep up the effect. He regards the treatment as undoubtedly specific. D.

Orientalism.—Dr. Work Dodd contributes a most interesting article to the *Lancet* for June 23rd. with the above title. In it he describes cases in which a gradual transition from a European to a Mongolian type took place. The first patient was seen for the first time in 1898, and was then a strong vigorous man, weighing over sixteen stone, was of a florid type and had light brown hair. He was at that time operated on for ptosis and left hospital soon after. He returned in June, 1899, and was then found to be much changed in appearance. He was only 11 stone 11 lbs., in weight, his hair was of a mousy colour, and no longer grew rapidly; he was more or less apathetic and his general facial aspect had gained for him the soubriquet of "The Japanee" amongst his fellow workmen. At the present time he retains an Eastern appearance, and has developed certain nervous phenomena which may perhaps be ascribed to old syphilis of which there is a definite history. Sexual desire is absent, and the testes are atrophied,; the thyroid gland cannot be felt, and there is semi-atrophy of the tongue. The second case was that of a man, æt. 48, with a doubtful syphilitic history, and with similar change in appearance, while in a third well-marked case a definite history of syphilis was present. The writer suggests that these cases may perhaps form a type of themselves which may be just as distinct and important as acromegalic and myxœdematous individuals. M.

The Radio-Therapeutics of Ringworm.—Sabouraud (*The Brit. Journ. Dermatology*, June, 1906) describes this treatment as devised and used by him at the Hospital of St. Louis, Paris. The method itself is very simple. and the results have been very encouraging. The ringworm patient having been examined and the patches recognised, the area which it is necessary to depilate is marked out by localisers. In cases where the entire scalp has to be depilated the head is marked out in circular areas, and each of these circles so marked out, is exposed in turn. After each exposure the part acted on is covered with a disc of lead, held on by an elastic band, to prevent the risk of exposing the same spot to a second application. The length of the exposure is timed by the alteration caused by the rays in the pastilles of Bristol paper coated with an emulsion of platino-cyanide of barium, in collodion with acetate of starch. These pastilles are placed in the path of the rays midway between their source and the scalp, that is to say, 7½ centimetres from the anticathode. When the exposure is completed the pastille should have changed colour to the standard tint of the radiometer. "This tint is such that when the pastille placed at 7½ centimetres has taken its colour the skin placed at 15 centimetres has received exactly the quantity of X-rays necessary to ensure the complete

depilation of the region without irritation, without dermatitis, and without compromising the ultimate re-growth of hair." In Paris Sabouraud has found this treatment most successful, the patch of ringworm being cured with certainty by a single exposure. It has been found possible to abolish in the hospitals a great part of the accommodation given up to ringworm and to apply this to other purposes. As an example of this result, Sabouraud gives the following figures. A ringworm patient treated in a hospital in Paris costs 2·80 francs per day to the Assistance Publique; treated in the way mentioned, the only cost is the X-ray exposures (of which from one to twelve may be required in order to denude the entire head), the cost of which is about 50 centimes each. "On January 1st, 1904, I was able to give up to the Assistance Publique a group of buildings capable of holding 150 beds. These 150 beds are to-day given over to two new departments of the hospital, one for medicine, one for surgery. Now a bed in a hospital in Paris represents on an average a capital of 10,000 francs, 150 beds represent therefore 1,500,000 francs. In six months I shall be able to give up to the Administration another group of buildings capable of holding about 100 beds—that is, a million of francs." K.

The Present Treatment of Syphilis.—Butt (*The Med. Chronicle*, June, 1906) discusses this problem in the light of his experience as an army surgeon both at home and in India. Butt is in favour of beginning the treatment as soon as any induration of the lymphatic glands can be detected, and continuing this treatment till resolution of these glands has occurred. He is in favour of the introduction of the mercury by subcutaneous or intra-muscular injection, and maintains that "so long as the excretory functions are normal one grain of metallic mercury, administered intramuscularly, may be looked on as a safe dose." If there is evidence of change in the local manifestations of the disease this dose is continued weekly, but should no change be apparent then an intermediary dose of half a grain is given on the third or fourth day, and if necessary repeated in increased doses. The injections are continued until the glands soften or lose their characteristic hardness, provided there is no evidence of mercurialisation. The cream now used in the medical service of the army, contains one grain of metallic mercury in ten minims. according to the following formula :—Hydrargyri, 1 oz.; Adeps lanæ (B.P.) 4 oz.; paraffin liquid (carbolic at 2 %) 10 oz. The injections are to be made above and along a line connecting the upper border of the great trochanters in each gluteal region alternately. K.

The Etiology of Eczema.—MacLeod (*Practitioner*, July, 1906) discusses this subject in the light of the more recent communications about it with the object of defining the present state of our knowledge on the subject. A precise definition of the disease does not appear to him possible, and he contents himself with a brief description of the complex symptoms to which the name is generally applied. At present there appear to be four opposing hypotheses concerning the nature and causation of eczema: (1) that it is parasitic; (2) that it is due to a variety of irritants both internal and external acting on a predisposed individual; (3) that it is due to nerve derangement; (4) that it is a symptom, not a disease, merely a cutaneous reaction to irritants in predisposed individuals. The explanation of eczema as due to local parasitic infection which at one time had the support of Unna has now been generally abandoned by dermatologists. The view that eczema is the cutaneous manifestation of some circulating toxin is at present in some vogue, but lacks proof, and the same may be said for the hypothesis of nerve causation. Many writers, notably Brocq, of Paris, and Hall, of Sheffield, maintain that eczema is merely a reaction of the neuro-cutaneous apparatus to external irritants in predisposed individuals, and this view MacLeod appears to adopt provisionally, while counselling us to avoid hasty generalisations, and to keep an open mind on the subject. K.

Landry's Paralysis.—Schütze records a case (*Berlin. Klin. Woch.*, 1906, No. 7) of acute ascending paralysis as a complication of typhoid fever. The patient was a Russian soldier, and was admitted with typical enteric symptoms. About eight days after the cessation of the pyrexia there was again a slight rise of temperature, accompanied by slight sensory disturbances, and followed by slight paralysis of the pelvic and abdominal muscles, and also of the muscles of the lower limb and trunk. Later there developed paralysis of the arms, Cheyne Stokes respiration, facial paralysis, and strabismus. Electric excitability was retained and there was no reaction of degeneration. Under treatment by mercury and other drugs, the symptoms rapidly disappeared within four weeks.

Donath (*Wiener Klin. Woch.*, 1905, No. 50) also records a case of Landry's paralysis which commenced with weakness of the feet and hands, and was rapidly followed by paralysis of the limbs, and by symptoms pointing to bulbar inflammation, namely dyspnœa, aphonia and dysphagia. Facial paralysis, and paralysis of the pupil reflex also occurred. Some sensory disturbances were present, and the electrical excitability of the muscles was increased. The cerebro-spinal fluid was increased in amount, and the patient lived four months after the onset of the symptoms. M.

Prurigo Lamphadenique.—Dubrieuilh reports (*Ann. de dermat.*, 1905, p. 665) two cases of this disease, bringing the total number of these on record up to eighteen in all. In both cases there was a combination of general lymph gland enlargement supposed to be of the nature of Hodgkin's disease, with the most intense and distressing pruritus. In the first case lymphomatous masses were present in the neck, axilla and in the mediastinum, causing in the last-named place collapse of the left lung. Microscopical examination showed the presence of numerous small lymphoid masses in the deeper portions of the cutis, and to the presence of these the writer attributes the sensory symptoms. He regards it as far more likely that such structures could cause the trouble than that the itching could be due, as was formerly supposed, to a toxin produced by the diseased glands. Treatment he found to be of little use, and was purely symptomatic. M.

Paroxysmal Hæmoglobinuria.—Langsteiner and Donath (*Zeitchrift f. Klin. Med. Bd.* 58, p. 173) have determined as the result of previously recorded investigations that the hæmoglobinuria in the above type of case is produced by the action of a hæmolysin. When one makes a mixture of red cells from a hæmoglobinuric or from a normal person, with some hæmoglobinuric serum and raises the mixture to body temperature hæmolysis at once takes place. This hæmolysis will only occur when the serum of a hæmoglobinuric is employed, and leads the authors to believe that the red cells are able to absorb a definite toxin from such serum. The authors have lately confirmed this result by the investigation of three new cases, bringing the total number up to six. They have also now examined 195 normal individuals, and in every case with a negative result. They are inclined to think that the toxin may be the result of syphilis, since they have obtained a history of old specific disease in all of their cases. M.

NOTE.—*A Summary will appear each week in the following sequence :*—(1) "*Recent Medical Literature.*" (2) "*Recent Surgical Literature.*" (3) "*Recent Gynæcological and Obstetrical Literature.*" (4) "*The Recent Literature of Physiology and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ILLEGAL TREATMENT OF DISEASE BY CORPORATIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I am instructed to forward you for publication the following resolution adopted by the Bradford Division of the British Medical Association at a meeting held on June 12th :—

"That in the opinion of this meeting it is highly undesirable that the City Council should carry on the treatment of disease for profit through officials at the Corporation Baths, who are not legally qualified medical practitioners, who treat diseases which are not of an epidemic character; that such practice is illegal, the Council having no powers authorising them to carry out such treatment; and that a copy of this resolution be forwarded to the Mayor, to the medical journals (*Lancet*, *British Medical Journal*, and MEDICAL PRESS AND CIRCULAR), and to the General Medical Council."

Hoping you will publish it, and thanking you in anticipation,

Believe me, yours sincerely,

Bradford, July 15th, 1906. JAMES METCALFE, Hon. Sec.

DR. J. E. SAWDON.—We have the series of Clinical Lectures by Mr. Jonathan Hutchinson in hand, and their publication in this journal will commence with the first number in August.

"THE NEWSIEST AND MOST READABLE MEDICAL PUBLICATION."

THE Editor of the *Medical Monthly*, in writing us that our weekly number had not reached him lately, says: "The MEDICAL PRESS AND CIRCULAR is one of the newsiest, most readable medical publications with which we are cognizant, and we take the liberty frequently of quoting from its pages." We thank our journalistic confrère for this expression of his opinion, which we hope is shared by our readers generally. We take it that the recent steady increase in our subscription list is a confirmation of the view of our correspondent.

L. H.—The cost of motor-bicycles and their handiness are recommendations, but you will find that for regular use a car will prove the better investment. Nevertheless, we know of one that has been in pretty hard use for over two years, but we think this must be exceptional.

R. S. T.—The book is published by Longmans, Green and Co., 39 Paternoster Row, E.C.

QUALITY OF CITY OF LONDON MILK.

AT the meeting of the Court of Common Council on Friday, the Chairman of the Sanitary Committee, in answer to a question with reference to the adulteration of milk in London, said that the last annual report of the Medical Officer of Health for the City showed that the ratio of adulteration was rapidly decreasing. In 1901 it was 21 per cent.; in 1902, 13·3 per cent.; in 1903, 11·6 per cent.; in 1904, 7·5 per cent.; and in 1905, 7·5 per cent. The average for the whole Metropolis was 12·5 per cent. Consequently, if a man wished to drink milk, he should come into the City to do so.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 18th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. P. Stewart: Recurrent and Transient Palsies.

THURSDAY, JULY 19th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Mr. T. Walker: On the Methods of Estimating the Function of the Kidneys.

FRIDAY, JULY 20th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. M. Yearsley. Clinique. (Ear).

Vacancies.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. Applications to the Director, School of Medicine, Cairo, Egypt.

Bradford Poor Law Union.—Resident Assistant Medical Officer. Salary £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22 Manor-row, Bradford.

Herefordshire General Hospital.—House Surgeon. Salary £100 per annum, with board, furnished apartments, and washing. Applications to W. A. W. Price, Secretary.

University of Manchester.—Junior Demonstrator in Physiology.—Salary £100 per annum. Applications to the Registrar.

Victoria Hospital, Burnley.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Sec., 7 Grimshaw Street, Burnley.

The Hartlepools Hospital. House Surgeon. Salary £100 per annum, with board, washing, and lodging in the Institution. Applications to Robert Edger, Secretary, 15, Town Wall, Hartlepool.

Medical School, University College Hospital, London.—Secretary. Salary £150 per annum. Applications to the Secretary of the Hospital.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, &c. Applications to Albert Edward Booker, Clerk to the Guardians, Union Offices, Westbar, Sheffield.

Lincoln Lunatic Hospital.—Assistant Medical Officer. Salary £100 per annum, with board, &c.—Applications to the Medical Superintendent, The Lawn, Lincoln.

East Riding Lunatic Asylum, Beverley.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Applications to C. W. Hobson, Clerk to the Visiting Committee, Beverly.

Windsor and Eton Royal Dispensary and Infirmary.—House Surgeon. Salary £120 per annum, with residence, board, laundry, and attendance. Applications to Geo. P. Cartland, Secretary.

Hospital for Sick Children, Newcastle-on-Tyne.—Male Resident Medical Officer. Salary £100 per annum, with board, lodging, and laundry. Applications to Alf. E. Birch, Secretary, Secretary's Office, Hospital for Sick Children, City Road, Newcastle-on Tyne.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Pathologist and Registrar. Salary £100 per annum. Applications to W. M. Wilcox, Secretary.

Preston Royal Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and washing, &c. Applications to Walter Davies, Secretary, 5 Winckley Street, Preston.

The Cambridgeshire, &c., Asylum.—Second Assistant Medical Officer. Salary £120 per annum, with board, lodging, and attendance. Applications to T. Musgrave Francis, Clerk to the Visitors, 18 Emmanuel Street, Cambridge.

Royal National Hospital for Consumption, Ireland.—Two Physicians as (1) Resident Medical Officer; (2) Assistant Medical Officer. Salaries £100 and £50 per annum respectively. Immediate application to the Secretary, 13 South Frederick Street, Dublin. (See advt.)

Appointments.

FERGUSON, ROBERT J., M.D., M.Ch., M.A.O.R.U.I., F.R.C.S.Eng., Gynæcological Registrar to the Kensington General Hospital.

GRAHAM, J., M.B., Ch.B.Edin., Clinical Assistant to the Chelsea Hospital for Women.

HUSTLER, G. H., M.B., Ch.B.Leeds, Assistant House Surgeon at the Royal Devon and Exeter Hospital, Exeter.

LAING, E. A. R., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Rochford District of the county of Essex.

MACKINTOSH, F. I., M.B., M.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.

ROSE, FRANK A., M.B., B.C.Cantab., F.R.C.S.Eng., Assistant Surgeon to the Hospital for Diseases of the Throat, Nose, and Ear, Golden Square.

SAWYER, JAMES E. H., M.A., M.D.Oxon, M.R.C.P.Lond., Casualty Assistant Physician to the General Hospital, Birmingham.

SHEPPARD, AMY, M.B.Lond., D.P.H.Cantab., Ophthalmic Surgeon to the New Hospital for Women and Children, Euston Road.

STEVENS, W. MITCHELL, M.D.Lond., M.R.C.P.Lond., Lecturer in Materia Medica and Pharmacology to the University College of South Wales and Monmouthshire, Cardiff.

Births.

CORY.—On July 10th, at Manor House, Soham, Cambs., the wife of C. G. Cory, M.R.C.S. and L.R.C.P., of a son.

FIELD.—On July 11th, at Zurich, the wife of H. Havilland Field, M.D., of a daughter.

KING.—On July 10th, at St. Leonards, Osmaston Road, Derby, to Dr. and Mrs. J. W. King—a son.

PRIDMORE.—On July 12th, at "Villa d'Este," Ryde, Isle of Wight, the wife of John Walter Pridmore, M.R.C.S., L.R.C.P.Lond., of a daughter.

Marriages.

ATKINSON—ELLIN.—On July 10th, at St. Andrew's Church, Sharrow Sheffield, William Atkinson, M.A., M.B., M.R.C.S., L.R.C.P., youngest son of J. P. Atkinson, Esq., M.D., Saffron Walden, to Constance, youngest daughter of Arthur R. Ellin, Esq., of Sharrow, Sheffield.

CAIE—KILNER.—On July 10th, at St. Mary's Church, Bury St. Edmunds, by the Rev. H. Ingate Kilner, Rector of Saxham Parva, William James Caie, M.A., M.B., Ch.B., elder son of the late Rev. William Caie, of Aberdeen, to Susan Christina, eldest daughter of Charles Scott Kilner, M.B., C.M., D.P.H., of Bury St. Edmunds.

NEWBOLT—ELLIOT.—On July 11th, at St. Bride's Church, Liverpool, by the Rev. Bernard C. Jackson, M.A., George Palmerston Newbolt, M.B., F.R.C.S., of 42 Catharine Street, to Lilia, only daughter of the late John Elliot, Esq., Canonbie, Dumfriesshire.

SIDDONS—WALSH.—On July 11th, at St. Augustine's Church, Edgbaston, Reginald Alfred, second son of Alfred H. Siddons, of Highfields, West Bromwich, to Mary Elizabeth Jane, only daughter of the late Saml. Walsh, B.A., M.B., L.R.C.S.I. (T.C.D.), and Mrs. Stubbins, of Edgbaston.

Deaths.

BREACH.—On July 11th, at Yattendon, Berks, James Henry Breach, M.R.C.S., aged 51.

MAY.—On July 12th, at Slough, after years of suffering, Louisa daughter of the late Geo. Hy. May, M.R.C.S., of Exeter.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, JULY 25, 1906. No. 4.

NOTES AND COMMENTS.

Four Lectures by Mr. Jonathan Hutchinson.

WE have much pleasure in drawing attention to a series of four clinical lectures by Mr. Jonathan Hutchinson which have been specially reported for THE MEDICAL PRESS AND CIRCULAR. The series will commence in our forthcoming issue of August 1st. A special interest will be attached to these articles inasmuch as two of them deal with various phases of syphilis, one being the transmission of that malady to the third generation, and the other its relation to tuberculosis. The subjects of the remaining two lectures are tuberculosis in relation to diseases of the skin, and affections of the same organ caused by insects. The clear, learned and philosophical treatment of these subjects by so distinguished an authority cannot fail to render these articles of widespread interest.

Pregnancy and Murder.

OUR readers may remember the case of a woman tried at the last Cornwall Assizes, and sentenced to death for murder. The execution was postponed by the judge on account of pregnancy, a plea which was duly put forward by the defence. The child had since been born, and lived only a few hours. At the inquest the medical officer said that the child was born prematurely, and that in view of her condition the woman ought never to have been tried until after the confinement. We are glad to notice that this opinion met with a sympathetic reception at the hands of the Coroner and jury, and we hope it will be brought before the Home Secretary. It is a relic of feudal barbarity that a woman advanced in pregnancy should be subjected to the awful ordeal of a trial for her life, and it is small wonder that a wretched infant prematurely born as the result of the mother's anxiety and trepidation should not survive his birth for twenty-four hours. When it is considered that a pregnant woman may be charged with a murder of which she is perfectly innocent, the imagination revolts.

Removal from Hospital without Legal Consent.

ANOTHER isolation hospital case which raises a practical point of some interest occurred lately at Edinburgh. It appears that a boy named MacKenzie was certified to have diphtheria and removed to the Loanhead Fever Hospital. His mother visited him at the hospital, and, being dissatisfied with things, came with his father the next day and removed the boy. The hospital being a long way from their home, a cab was taken for the invalid. The father and mother were summoned at the Sheriff's Court for removing their boy "without legal consent," and though the Sheriff spoke sympathetically he was obliged to fine them both. Now if a patient can legally be detained in a hospital, as this case seems to show is possible in Scotch law, the isolation hospital assumes an importance in national life that cannot be overlooked, for it becomes like a prison or lunatic asylum, but without their safeguards. In England there is no power of detention without a magistrate's order, and even then we suspect most medical superintendents would be loth to detain a patient forcibly.

Medical Reports on Police Witnesses.

A MATTER touched on in these notes last week has received further illustration at Salford. The Stipendiary of that town, while hearing a remand case of assault, was told by the Chief Detective-Inspector that sufficient information as to the patient's state was not forthcoming from the hospital. The medical officer was then called, and the magistrate asked him why the constable could not be given the information at the institution in question. To this Dr. Wardleworth replied that a medical man was entitled to a guinea for a report on a case, and that in this particular instance the question was one of prognosis and not merely one of how the patient was progressing. In the course of further argument it appeared that one policeman came and asked as to the patient's state, of which he was duly informed, and that then another officer arrived and asked questions as to his probable progress. Dr. Wardleworth told him that he was willing to give such a report in the usual form and at the usual fee. Eventually the magistrate remanded the prisoner and said the police would make inquiry as to the child's state from time to time. Here again a matter involving skilled opinion was in question, and the State, as represented by the magistrate, practically refused to tender the medical officer a fee for giving an expert report. It is characteristic of the usual sweating of the profession that even the officers of the law pooh-pooh the bare idea of paying for a medical opinion.

LEADING ARTICLE.

THE NEWSPAPER PRESS AND QUACKERY

HOWEVER difficult it may be to believe it, we are bound to assume, and we shall at any rate for the present assume, that the consummate men of the world who own and manage the great London papers, are not fully aware of the nature of the traffic in which they are assisting by the indiscriminate admission of quack advertisements to their pages. If we have not in former articles already said enough to show them the need at least for serious inquiry, we trust that in the end we shall have done so. We have previously pointed out that the mischief wrought by quackery may amount to mere pocket-picking, or to the direct or indirect causation of unnecessary suffering, misery, and death. The least harmful form of quack imposture is that confined solely to the concoction and sale of such things as hair lotions and cosmetics. Some of these preparations may be pleasant to use, but in so far as they promise to make hair grow or to improve the condition of the skin they are with rare exceptions easily demonstrable swindles. It is especially fraudulent in many cases to undertake the cure of a "bad complexion" by local treatment of any kind alone, since the conditions often depend upon disorders of the general health. Many vendors of cosmetic preparations, however, use them as a bait to attract customers for personal treatment. The dupes are nearly all women —women simple, weak, or foolish. The quack with a sufficiently keen eye for character has little difficulty in picking out those who can be most easily robbed. Cases of extortion of this kind can be related by most family doctors of wide experience to whom the details have been confided by patients. The safety of the quack in such instances lies in the fact that there is hardly any wrong a sensitive or nervous woman will not endure rather than publicly expose her folly in a court of law; but every now and again such an exposure does take place. For instance, a few months ago a woman made an appeal for assistance to a London magistrate. She stated she was a lady's maid, and having developed some unsightly affection of the skin of the face, detrimental to her employment, she had been induced by an advertisement in a prominent London paper which she named to apply to a lady skin specialist. It is significant that the quack's name was not given in any newspaper report of the case. The quack, whom the woman imagined was a qualified doctor, had undertaken to cure her for £25. She paid in advance the sum demanded, a great part of her savings, and having undergone the treatment found her malady worse than before. The magistrate declared that he was unable to assist her. In the rare cases of a similar kind in which better advised legal methods are adopted the quack is usually induced to give up his plunder, and even to pay damages as well, rather than have his methods brought to light in a court of law. Cosmetic quackery, "beauty doctoring," and quack dentistry—the fixing of marvellous artificial teeth—are among the safest games for the impostor to follow, first because of the gullibility of the women patients and the ease with which they can be intimidated; and secondly, because, however gross the malpractice, the possible death of a patient and a charge of manslaughter need hardly be considered. These examples of sordid rascaldom may no doubt be easily scoffed at by the cynical, but, admitting that the injury to health to which their practices give rise is not commonly serious, it must be remembered that, in the words of a *Times* leading article, "they bring about the still greater evil of maintaining in prosperity and luxury some of the most complete and finished of the many impostors who are parasitic upon modern civilisation!" The rapid increase of these social pests at the present day is mainly due to the fact that leading papers, including the *Times*, now freely accept almost every class of quack advertisement. The editors dare no longer attack quackery. They can never be sure that a paid puff of the quack they are denouncing may not appear in the same issue of their paper or even in juxtaposition to their article, and vouched for by the conductors of the advertising department. The cosmetic quack, the hair restorer, the "beauty doctor," the quack dentist, and their tribe are only less criminal than other species of medical quacks, because the field of their operations does not oblige them to tamper with matters of life and death. To the more serious forms of quackery we shall return in future articles.

NOTES ON CURRENT TOPICS.

Science and the School Hamper.

TRULY there is nothing either too great or too small to escape the attention of omnivorous science. Every detail of our lives, the air we breathe, our food and drink, our clothes, exercise, sleep, our homes, workshops, offices, schools, in a word, everything that enters into the complex modern environment, becomes the subject of an elaborate essay. Many a long-cherished usage has in this way faded out of existence beneath the ban of science. The three-bottle man has vanished along with the stage coaches, while wholesale capital punishment for trifling offences has given place to scientific criminology. Science has so far purified water supplies that cholera has been banished from the United Kingdom, although water-borne typhoid fever is likely to thin our ranks so long as we are content to drink sewage-polluted river water in London and in various other great cities. In the long run, however, even pure water will come to sanitarians who are content to wait. Meanwhile we are sharply reminded by Dr. Symes, at the Bristol Sanitary Congress, that nothing is sacred to the restless hand of Science. Her last and, in some ways, most audacious feat has been to attack the school-

boy's hamper. The gist of the complaint is that children, after the rich home fare of the holidays, cannot relish plain school food. They complain to parents, who forthwith despatch extra pocket-money and double-sized hampers. "In either case," says Dr. Symes, "the result is the same; namely, that the child eats a supply of undesirable food between meals and still further neglects the food provided at meal-times." In our early days the schoolboys with whom we were acquainted tackled both supplies without turning a hair. To our mind there could hardly be a more certain sign of physical degeneration in the nation than the standard of public school health that leads an eminent authority to threaten one of the earliest and most prized of our national landmarks—the school hamper.

Motors and Influenza.

IT is usual to associate influenza with the warmer months of the year—a belief founded on bitter and oft-repeated experience. Of late medical men have learnt that this most undesirable catarrh is associated with summer road dust. The connection is probably due in nine cases out of ten to an inflammatory condition of the nasal mucous membranes, set up by the presence of minute irritant particles. If all this be true it follows that motors, which raise dust galore, to say nothing of their noxious fumes, must be answerable for an untold amount of influenza. As a matter of fact, the whole of the United Kingdom at the present moment is being swept by a wave of influenza, happily of a somewhat mild type. The cause of the outbreak is most likely to be found in motor dust, which is distributed just as widely as the epidemic. Truly the havoc wrought by motors is manifold and endless.

The "Standard" and Quackery.

IN the *Standard* of July 16th appears a particularly obnoxious advertisement of an "Institute" for the cure of all sorts of diseases. This advertisement appears side by side with ordinary news, and from the type and get-up of the article it might easily be mistaken for such by an ordinary reader. It is headed "Startling Advance in the Cure of Disease—Medical Enthusiasm," and it is not till the eye reaches the bottom of the column that the abbreviation "[Advt.]" modestly suggests that all the wonderful things that have been related in the article are there for a specific purpose. The column is written on the best pattern of the *Times* advertising staff; a number of vapid generalities about the advances in medicine; the ailments that flesh is heir to, and the scientific treatment of disease, are given forth with an air of authority as transparent as it is offensive, when the real object of it all is considered. A treatment, inexpensive and suitable for home application, has been brought out and received the approval of the medical profession, not only in Great Britain, but also all over the Continent, so that it has resulted in "practically universal adoption." Now stuff of this kind should carry its own condemnation with it. If the treatment "may be undertaken in the patient's own home with almost the certainty of a cure, even in the most obstinate cases," what is the use of an "Institute"? Moreover, if the treatment has resulted in "practically universal adoption," what need is there to advertise it and to have a special "Institute," run for the benefit of the advertisers, to carry out what is "practically universally adopted"? We do not know whether the lack of inventiveness of advertisement writers, the want of intelligence of the public, the rapacity of newspaper owners for advertisements, or the greed of quacks is suggested to us most strongly by such poor, sorry nonsense as this. But the points in the advertisement that we object to most strongly are the offensive suggestions that this precious treatment is hailed with enthusiasm by the medical profession, and the way in which an honoured name such as that of Sir J. Crichton-Browne is dragged in. We have no hesitation in saying that such an advertisement is as lacking in good taste as it is in good sense, and that the *Standard* has cause to blush for the great traditions of the past when it inserts stuff like this to read as ordinary newspaper matter.

Liability for Infection.

A CASE fraught with a most important issue to medical men was decided last week in the Court of Appeal. The facts have been already mentioned in THE MEDICAL PRESS AND CIRCULAR, but in view of the appeal, full comment could not be made. The plaintiffs were an auctioneer and his wife, a Mr. and Mrs. Crier, who sued Drs. Currie and Hope, medical practitioners in partnership at Ealing, for damages on the ground that Dr. Currie had infected Mrs. Crier with scarlet fever while attending her in her confinement. The facts that Dr. Currie had seen a scarlet fever patient before attending Mrs. Crier, and that Mrs. Crier had contracted scarlet fever were not in dispute; the point was, did Dr. Currie infect her, and if so, did he do so negligently? At the trial the jury found that Dr Currie had taken all the precautions usually considered necessary between visiting the scarlet fever patient and attending Mrs. Crier, and this verdict, we are glad to see, was upheld in the Court of Appeal. Every medical man in general practice has his life worried by the question as to how far he is likely to carry infection from some source or another to his confinement cases, and though it rarely happens, it is inevitable that in the absence of full knowledge of prophylaxis and through lack of opportunity to carry out every conceivable precaution, infection should be conveyed from time to time. The world would not be human if certainty were attainable. It is, then, comforting to know that it will be held sufficient protection for a doctor if he takes all reasonable precautions in the matter of disinfection. Clearly it is not always possible

in the rush and hurry of practice to take all ideal precautions. In other words, all that is expected of a doctor is that he should do his best, as Dr. Currie did in the case in question, and that the risk, infinitesimal as it is, belongs to the patient, and must be taken by him or her as risks are taken in everyday life. We congratulate Dr. Currie on successfully vindicating not only himself, but his profession. Any other decision would have pointed to the necessity of one set of general practitioners to attend fevers and another to conduct midwifery cases!

Manchester Food Inspection.

THE way in which commercial interests unblushingly enter the lists against those of public health was forcibly illustrated last week—not at Chicago—but before a committee of the House of Commons. The occasion was the consideration of a Bill presented by the Local Government Board confirming a provisional order granting the Manchester Port sanitary authority power to inspect foodstuffs entering the port, and this necessary authority was vehemently opposed by the Manchester Ship Canal Directors on the ground that such inspection would place Manchester commercially at a disadvantage with Liverpool. It appears from the evidence that the Liverpool Port authority have not the power sought by Manchester, and it was argued on behalf of the Manchester Ship Canal that shippers would send their foodstuffs to Liverpool in preference to Manchester if inspection were known to take place at the latter port. Although it is to be hoped that Liverpool will immediately come into line in the matter, the action of Manchester suggests to us a deplorable cynicism with regard to the health of the country. We should hardly have expected a large commercial company publicly to object to food inspection on such absolutely unworthy grounds. We are glad to say that the Commons committee unanimously confirmed the order.

The British Medical Association and its Charter.

WE observe that the Council of the British Medical Association has decided to recommend that the proposed application of the Association for a Royal Charter be postponed for twelve months. In thus shelving the question we believe that the Association is acting wisely. There is no doubt that to many of the members it had not been made clear what advantages they would gain in lieu of the safeguards at present afforded them by the Companies Acts. As long as the Association remains a registered company, it is subject to the ordinary conditions of company law, and these conditions have as their object the protection of the property of the shareholders against a dominant clique or party. Some very strong reason would have to be brought forward to prevail upon members to throw away these safeguards, and we are bound to say that no such reason was made evident. As far as could be judged, the demand for a Royal Charter was merely the expression of the foolish vanity of a few people, who thought, without considering the question, that the importance and prestige of the Association would be enhanced by its possession.

PERSONAL.

AFTER due consideration of all the facts of the case, the Attorney-General has ordered a *nolle prosequi* to be entered with reference to Dr. George Robert Adcock, whose trial for the alleged manslaughter of Major Whyte, D.S.O., took place at the last sessions of the Central Criminal Court.

BY the election of Mr. Henry Morris as president of the Royal College of Surgeons, the Middlesex Hospital now has the honour of including on its staff the presidents of both the Royal Colleges of Medicine and of Surgeons.

WE regret to have to record the death of Mr. Edward Rawlings, one of the founders of the Royal National Fund for Nurses, and for many years one of its most active supporters.

IT is commonly reported that Sir William T. Collins is to be one of the members of the Royal Commission on Vivisection. Sir William's keen work on the Vaccination Commission during the seven years that it sat doubtless contributed to his selection.

We understand that Lord Selby, better known to the public as Mr. Gully, will be chairman of the Commission.

IT is announced that Dr. McKenzie Johnston has retired from his post as Surgeon to the Ear and Throat department at the Edinburgh Royal Infirmary. Many old Edinburgh men will hear the news with regret.

MR. W. L. SAUNDER, the secretary and general superintendent of the Manchester Royal Infirmary, who died early this month, had held his post for nearly thirty years.

AT the annual meeting of the Leeds Medico-Chirurgical Society. Dr. H. H. Bampton of Ilkley was elected president for the year.

DR. A. A. MARTIN of Eastbourne was the object of a savage attack by an insane patient in the street last week. Dr. Martin, who has recently received a commission in the volunteers, defended himself with great bravery and eventually overpowered his assailant.

THE news of the death of Dr. Mary Putnam Jacobi has just reached this country. As one of the pioneers of women's medical education, as professor for ten years in the Women's Medical College at New York, and as the wife of a distinguished husband, Dr. Mary Jacobi was well-known in many circles.

ON the occasion of his marriage a handsome presentation of silver plate has been made to Dr. John Mortimer by the staff of the Exeter Dental Hospital, an institution to which Dr. Mortimer is consulting physician.

DR. W. MUNCH will preside at the congress on child study to be held at Berlin early in October.

THE death of Dr. John W. Dodds of Cramlington village was found to have occurred through an overdose of belladonna accidentally taken.

A CLINICAL LECTURE
ON
CHRONIC RHEUMATISM AND RHEUMATOID ARTHRITIS.

By J. ODERY SYMES, M.D., D.P.H.
Assistant Physician and Bacteriologist, Bristol General Hospital.

IN no group of diseases is our nomenclature more confused than in the rheumatic group. Under the title of rheumatoid arthritis we have certainly two, and probably more than two, distinct diseases; whilst chronic rheumatism includes not only a fibrositis affecting muscles and the ligaments of joints, but also relapses from and sub-acute attacks of rheumatic fever, and any stiffening of or thickening in the joints which may follow rheumatic fever. Muscular rheumatism you are all familiar with in the common form of lumbago and torticollis, conditions not at all difficult of diagnosis. When, however, the muscles of the shoulder-joint are implicated (omodynia) it is often difficult to decide whether the pain lies in the articulation or in the overlying structures. This brings to us the question, "Is there a true chronic articular rheumatism?" If all cases of sub-acute rheumatism, all cases of gout, gonorrhœal rheumatism, and of rheumatoid arthritis are eliminated, joint conditions which can be styled chronic articular rheumatism will be very few, and personally I am inclined to doubt the existence of such a disease. Cases of chronic swelling, stiffness, and pain in the joints, following an acute febrile attack with arthritis, are in the majority of instances early types of rheumatoid arthritis, a fact which is unfortunately only too often overlooked. Spender defined rheumatoid arthritis as "a progressive degeneration of joints of a special kind, accompanied by atrophy of some structures and hypertrophy of others. The course of the disease is variable, but is ordinarily towards irrevocable damage and ruin of the structures involved." Obviously this definition might be made to include a number of widely different joint diseases, but we can clearly differentiate two varieties of rheumatoid arthritis, one (osteo-arthritis) in which proliferation of bone is a characteristic, and the other (fibro-arthritis) which is associated with increase of fibrous tissue in and around the joint. It is, however, unlikely that chronic rheumatism would be confounded with rheumatoid arthritis with well-marked bony and fibrous changes. It is only in the early stages or in very slight cases of rheumatoid arthritis that the mistake is likely to be made, and I purpose to day to indicate to you the points which should enable you to make a correct diagnosis. Looking first at the predisposing causes, you will find that the majority of cases of muscular and chronic rheumatism occur in adults, and more commonly in men than in women, whilst in rheumatoid arthritis the order of things is reversed. Pains in the limbs and joints in women at the climacteric, however, are mostly rheumatoid in nature. Sufferers from chronic rheumatism will frequently give a personal or family history of past rheumatic fever, of tonsillitis or of chorea, and the evidences of endocarditis will be detected by physical examination. Cases of rheumatoid arthritis associated with the rheumatic phenomena are on the other hand exceptional, but you will find this disease not infrequently dating from an accident, or injury, a confinement, an attack of epidemic disease such as influenza, or associated with some slight suppurative or ulcerative lesion. Anything, therefore, which permits of the possibility of a chronic pyæmia or toxæmia should lead you to suspect the presence of rheumatoid arthritis. The most frequent causes which are overlooked, especially among out-patients at the hospital, are endocervicitis and endometritis, foul conditions of the teeth and gums, suppuration in the accessory sinuses of the nose, and intestinal dyspepsia associated with constipation. The pains of both rheumatoid arthritis and chronic rheumatism are much influenced by changes in the weather, intensified by cold and damp, and relieved by warmth. Chronic rheumatism is the more readily relieved by change of locality, being favourably affected by removal to a dry, sunny, and bracing neighbourhood.

In the signs and symptoms of the disease there are to be found several distinctive features. A persistent pulse rate of from 90 to 100 without corresponding elevation of temperature; the presence of sweating on hands, feet, and face, or of deep pigmentation or freckling of the skin; exaggeration of tendon reflexes—all these are characteristic of rheumatoid arthritis; and the probability is increased if associated with the pains there be vaso-motor symptoms resembling those seen in Raynaud's disease, and if neuralgia be present, especially neuralgia extending up from the neck over the back of the head. The importance of looking for these signs lies in the fact that they can be detected before there are any definite changes to be found in the joints. Vague, indefinite pains in joints or limbs associated with several of the above mentioned symptoms should always be regarded as indicative of rheumatoid arthritis.

Symmetrical distribution of the joint lesions, especially if these are persistent, and if the smaller interphalangeal or metacarpo-phalangeal joints are involved, is suggestive of rheumatoid arthritis. It is, too, characteristic of this disease that the pain is often worse at night when the patient is in bed, and the sufferer in order to obtain relief feels that he must get his arms and hands from beneath the bed-clothes. In old people chronic rheumatism is often very intractable, invading fresh groups of muscles, and gradually spreading until the body feels as if it had been beaten all over. There is stiffness on waking in the morning which gradually improves as the day goes on, only, however, to return after the night's sleep. With this form of rheumatism there is an elevation of temperature of about a degree or a degree and a half, much constitutional disturbance, mental depression, and dyspepsia with flatulence and constipation. Such a condition may persist for weeks in spite of remedies. It is in these protracted cases in elderly people that you will find the nodules of white fibrous tissue which are characteristic of chronic rheumatism. They vary in size from a pea to an almond, and lie on or in the muscles. The skin over such nodules is not reddened, but they are tender on pressure. The fascia on the outer side of the thigh, the lumbar aponeurosis, the occipital and shoulder muscles are the most frequent sites of these nodules. Practically these nodes are not of great value from a diagnostic point of view, for they are only rarely present and require skilled manipulation for their detection. The masseur will frequently be able to find them when the physician cannot do so. Similar fibrous nodules I have seen in rheumatoid arthritis, but not lying in or on the muscles, but over the metacarpo-phalangeal joints or in tendon sheaths.

Vague pains in articulations flitting from joint to joint are suggestive of chronic rheumatism rather than rheumatoid arthritis, for in the latter disease the pain is persistent and does not show the same tendency to clear up quickly and pass to a fresh site. Rapid wasting of muscles with but slight sign of local disease is met with in rheumatoid arthritis, and is to be distinguished from the atrophy of muscles which comes on as a result of disease in severe cases of muscular

rheumatism. The former is partly due to spinal and peripheral nerve changes, and is much the more severe in character.

Subjective sensory symptoms of a peculiar character are very frequently met with in the early stages of rheumatoid arthritis. They are of different kinds. Thus there may be complaint of pain shooting from the ball of the thumb to the elbow, pins and needles in the extremities, a feeling as if the hands and arms had been plunged into cold water, numbness, weakness, a sensation of discomfort and restlessness in the limbs. All such are characteristic of rheumatoid arthritis, rather than of chronic rheumatism; indeed in the latter I have never met with such symptoms apart from neuritis.

I have now put before you the chief points that help us in the making a diagnosis between rheumatism and rheumatoid arthritis in the early stages. These remarks do not apply to the well-marked cases of fibro- or osteo-arthritis. In such no difficulty generally presents itself. But you cannot afford to wait for the establishment of such joint changes as will render your diagnosis certain, for if you do your treatment will be of little service to your patient, as it is pre-eminently in the initial stages of the disease that amelioration of the condition is to be expected. Rheumatisme fibreux is a form of chronic rheumatism affecting the palmar fascia and leading to Dupuytren's contraction. It is generally found in young girls and is associated with old-standing endocarditis. Rheumatoid arthritis is met with in children, and there is sometimes with it an enlargement of the spleen and of the lymph glands, signs which would sufficiently distinguish the condition from chronic rheumatism. It is sometimes said that the pains of chronic rheumatism are relieved by salicylate compounds, whilst those of rheumatoid arthritis are not. This, however, is not the case, for many sufferers from rheumatoid arthritis experience much relief whilst taking sodium salicylate or aspirin. The salicylates, it should be remembered, do not cure rheumatism either acute or chronic; they relieve pain and keep the morbid process in check; more than this should not be claimed for them. Chronic rheumatism has several distinctive complications, chief amongst which I should mention sciatica, tonsillitis, pharyngitis, rhinitis, and laryngitis. Iritis is frequently spoken of as rheumatic, but too much reliance cannot be placed on this symptom, for it is a not uncommon accompaniment of rheumatoid arthritis.

The importance of correctly diagnosing between these two diseases lies in the fact that they demand very different treatment. The administration of salicylates and the ordering of massage is the routine treatment of any kind of joint or muscle pain by a large number of practitioners. Under such a system it is found that many persons are made worse by the rubbing, and that when the salicyl compounds are withdrawn the pains immediately recur.

Treatment.—In general the indications for treatment in the two diseases are as follow:—Chronic rheumatism calls for an eliminant course of treatment, whilst rheumatoid arthritis is most benefited by the exhibition of tonics.

Thus we see that in chronic rheumatism the drugs employed are the salicylates, alkalis, guaiacum, sulphur, potassium iodide and ichthyol—drugs increasing the secretions of the bowel, skin, liver, and kidneys.

At the outset of an attack of muscular rheumatism, the patient should be given a dose of calomel (as Plummer's pill) and a smaller dose should be given every third and fourth succeeding night. The first acute pain may be relieved by fomentations, hot baths, or anodyne applications and by the administration of aspirin or sodium salicylate in full doses. If the pain recur each time the salicyl compound be withdrawn, then recourse should be had to one or other of the drugs before mentioned. A mixture which is very largely used in the outpatient department consists of tinct. colchici 10 minims, pot. iod. 3 grains, pot bicarb., 10 grains, tinct. guaiaci ammon. 15 minims. mucli. acacia q.s., aquam ad $\bar{3}$; this is rather a nauseous draught to take three or four times a day, and as an alternative I sometimes use the old pulv. guaiaci co. (Chelsea Pensioner) in 30-grain doses. It contains equal parts of guaiacum resin, precipitated sulphur, heavy magnesium carbonate, gum acacia, and potassium carbonate. Guaiacum resin may be administered as a tabloid or in cachet, but it is more effectual when combined with other eliminants such as sulphur. Doses of ten grains of sulphur and ten of guaiacium resin combined administered four times daily after meals are most efficient. Recently the oxybromides of some of the metals have been recommended for chronic articular pains, but I have found no benefit follow their use.

Side by side with the administration of drugs there must be an effort made to improve the condition of the muscles and to increase the eliminative powers of the skin. This is best done by a course of Turkish baths taken on alternate days and followed by good rubbing. Some patients state that they cannot take Turkish baths without feeling faint and giddy, and for these vapour baths or simple daily massage may be presented. The rubbing should be continued for at least three weeks, and the patient should be warned that the muscles may feel even more painful than formerly after the first two or three applications. If the rheumatism does not yield to this treatment, the high frequency current given on alternate days sometimes yields excellent results.

To complete convalescence a change of air to a dry warm mildly bracing climate is desirable, and the patient should be ordered to take moderate exercise such as golf, walking or riding.

It will be seen from the foregoing that the treatment of chronic rheumatism is tedious and trying to the patient, and for this reason the best results are, I think, obtained by residence at some home or foreign spa. In this country Harrogate, Llandrindod Wells, and Woodhall Spa are suitable places in the summer months, whilst during the colder months of winter and spring patients do best in a milder climate such as that of Clifton, Cheltenham, Bath.

Aix-les-Bains, Contrexeville, and Baden bear high repute for the treatment of chronic articular and muscular rheumatism.

Sufferers from chronic rheumatism should be warned against free indulgence in animal food, and their diet generally should be lighter than that of persons in good health. The occasional use of some alkaline table water should be recommended, and alcohol in any form forbidden. Moderate systematic exercise, frequent warm baths, and the wearing of warm clothing will lessen the risk of recurring attacks. Damp clay soils, absence of sunshine, sudden large variations of temperature, are all predisposing causes of chronic rheumatism and where possible the sufferer should reside so as to avoid these conditions.

I shall touch upon the treatment of rheumatoid arthritis only in so far as is necessary to point out the differences between the measures required for the successful treatment of this disease, and those which we have already considered. The one essential point in the treatment of rheumatoid arthritis is the discovery and removal of the primary focus of intoxication.

This intoxication may be bacterial in origin, or it may be the result of some error of metabolism, such as we associate with gout and arterio-sclerosis.

Unless this can be done all our efforts must be of a palliative nature, and aimed at the preservation of the general health of the patient until such a time as the poison shall have exhausted itself. A systematic examination of the patient should be made, the past history closely scrutinised, and every detail of the method of living ascertained. I would repeat that the conditions most commonly overlooked are septic conditions of the mouth, chronic inflammatory or suppurative lesions of the nose, throat or accessory sinuses; in women unhealthy states of the pelvic viscera, and

in both sexes persistent flatulent dyspepsia, more particularly associated with intestinal fermentation. If you glance through a list of drugs employed in the treatment of this disease, you cannot fail to be struck by the number of them which have a direct or indirect antiseptic action on the bowel contents, *e.g.*, creosote, guaiacol, guaiacol carbonate, salol, B. naphthol, sodium salicylates, methylene blue and iron. The success of the so-called Salisbury treatment depends in large part on the fact that by limiting the starch and sugar in the diet the fermentative changes are lessened, and the supply of the toxic material cut off. Chronic rheumatoid arthritis in elderly persons is often associated with arterio-sclerosis, the two conditions being alike excited by some error of metabolism. Once the source of infection is discovered and dealt with, the treatment of rheumatoid arthritis resolves itself into supporting and improving the general health by the administration of tonics, and by suitable climatic conditions, in restoring the mobility of the joints and improving the muscles by baths, rubbing, and exercises; and in regulating the diet and habit of living in such a way as to confer the greatest amount of benefit to the system generally, but more particularly upon the nervous system, on which the effect of the toxin is always so marked.

The point I wish to emphasise is this: that the treatment of chronic rheumatism is entirely different from that of rheumatoid arthritis. In the former an eliminant treatment is indicated, which if adopted in the case of the latter would only result in an aggravation of the disease; and whilst in chronic rheumatism the adoption of measures such as bathing and massage early in the disease is beneficial, in rheumatoid arthritis such procedures will in the early stages only tend to perpetuate and intensify the evil. There is one point I should like to mention to you in conclusion, namely, that however successful you may be in determining and removing the exciting cause of an attack of rheumatoid arthritis, you cannot hope, and you should not leave your patient to hope, that the old standing structural changes of osteo-arthritis with the resulting crippling can ever be repaired. Rheumatoid arthritis is not a disease from the treatment of which you may expect striking successful results ensuring the gratitude and admiration of your patients. You may check the progress of an old-standing case, but the structural changes and the personal discomfort remains, and if you are able to diagnose and successfully stop a case in the early stages the symptoms have probably been so slight that your patient is ignorant of the danger of life-long crippling from which he has escaped.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Jonathan Hutchinson, LL.D., Oxon. and Cantab., Hon. M.D. Dub., F.R.C.S. Eng., F.R.S, Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and the Royal London Ophthalmic Hospital on "The Transmission of Syphilis to the Third Generation," delivered at the London Hospital, June 13th, 1906.*

ORIGINAL PAPERS.

A STUDY OF HYDATIDIFORM MOLE: WITH THE RECORDS OF THREE TYPICAL CASES.*

By JAMES OLIVER, M.D., F.R.S.EDIN., F.L.S.,

Physician to the Hospital for Women, London.

DR. OLIVER desired, before reading his paper, to say a word or two about the theories of menstruation. He thought there was abundant proof, both clinical and pathological, that there was no such thing as a *decidua reflexa*. With regard to menstruation the usually accepted view was the denudation theory, which he did not believe could be maintained. In cases of retained menstrual fluid there was a strong case made out against the denudation theory. If that theory held good under those circumstances, one could accept it for all cases. One knew that menstrual fluid went on accumulating in cases of imperforate hymen, and where the cervix had become occluded and the uterus might be so distended with menstrual fluid that the tension would force the fluid through into the peritoneal cavity. He had operated upon cases in which the fluid had been forced through the Fallopian tube into the peritoneal cavity. If the denudation theory held true, the menstrual fluid would not accumulate in those cases, because the actual pressure of the fluid in the uterus when it was present in such large quantity would arrest the extravasation of blood from the capillary vessels which had been ruptured.

Hydatidiform mole consists in a more or less complete degeneration of the verrucose surface of the chorion whereby many of its processes become converted into cyst-like bodies—bodies which vary in size from a barley-corn to a walnut, but are seldom larger. Some authorities believe the change to be of a myxomatous character, but its exact nature has not yet been determined.

It occurs independently of any uterine influence, and is solely attributable to some aberration on the part of the germ-plasm. This is very evident, since this aberrant product has been known to develop in a uterus concurrently with another but a well-endowed oosperm, an oosperm which attained maturity, and was eventually expelled as a fully developed and living child; two germinal elements, *i.e.*, had been fertilised simultaneously, but their potency being very different, one pursued an abnormal, whilst the other pursued a perfectly normal course. Moreover, I have myself observed that to all intents and purposes conception may as readily succeed this as any other kind of abortion, the resulting gestation proceeding uninterruptedly and being terminated quite naturally.

However the change which produces a vesicular mole may be induced, it begins to assert itself at an early stage in the evolution of the ovum, between the third and sixth weeks of pregnancy, whilst the allantois is still active and before any marked physiological differentiation in the chorionic villi has taken place; hence it seldom happens that even a semblance of an embryo is detected amongst the débris. Towards the end of the third week of gestation the allantois becomes vascular, and rapidly thereafter the vessels of this structure extend to and invade the villi of the chorion, so that during a very limited period of its existence the developing ovum is everywhere placental, and at this stage the embryo, without the interposition of any so-called decidua reflexa, is nourished by these vascular processes which absorb nutriment directly from the endometrium generally. As these vessels thrust themselves into the chorionic villi they are accompanied by a portion of the external or mesoblastic layer of the allantois, a gelatinous-like structure which serves not only to bind the villous contents together, but plays an important part in maintaining the well-being of the ovum whilst the latter is universally placental. During the sixth week of pregnancy differentiation of the villi is effected; those which are destined to participate in the formation of the placenta undergo a remarkable change, and increase greatly in size,

* Read before the British Gynæcological Society, July 12th, 1906.

whilst those involved in the remaining four-fifths of the chorion begin at the same time to atrophy and, gradually declining, all trace of their existence is soon lost. Until this stage is reached the allantois and chorion have continued to act and react harmoniously upon each other, but about this time it so behoves the chorion to bestow its energy upon the endometrium, stimulating and arousing in it such vigorous local growth as is necessary for the evolution of the placenta, that the allantois is required to assume a more passive *rôle*. This transition may, however, induce a perversion of the latter's function, and the chorion being thereby prejudicially influenced the allantoidal vessels may eventually become more or less completely obliterated, and thus there may result the mole we are now discussing. Although functionally deranged, some of the placental and even some of the non-placental villi may excite such reaction in the uterine wall that a more or less intimate union may be established between the embryonic and maternal tissues, and the morbid processes connected therewith may prove troublesome not only during gestation, but after abortion. It is these morbid processes which are accountable for the more frequent occurrence of chorionic epithelioma after this than any other kind of gestation.

Hydatidiform mole may be observed at any time during the reproductive life of the woman, extremely early as well as very late. It may occur in a woman who previously has given birth to mature and healthy children only, or in one who has never before been pregnant.

In its early days this disorder is characterised by symptoms and signs which are essentially those of an ordinary threatened abortion, but later it may present more and more the characters of "a missed," or, as I prefer to call it, "a postponed" abortion, and this it may virtually become, for this product of conception may be retained for many months. In one of the cases recorded in this paper it was detained in the uterus eleven months, but the most prolonged case of "postponed abortion" which has come under my immediate notice was one in which the embryo, perishing about the tenth week of gestation, was not expelled until about the middle of the thirteenth month. In hydatidiform mole there is invariably the history of a more or less prolonged period of amenorrhœa, succeeded by a greater or less amount of discharge of an irregular and hæmorrhagic character from the external genitals, a discharge which may in no respect differ from that observed in an ordinary case of threatened abortion. In the majority of cases it is the continuance of this discharge which causes the patient to seek advice. For six weeks or as many months complete amenorrhœa may have been noted. Now, although the determining cause of menstruation is still unknown, yet the fact that this function is held in abeyance in cases of intra-uterine death so long as the product of conception is retained in the uterus is deserving of more than passing notice. I have elsewhere ("A Study of Four Full-time Ectopic Pregnancies." *Edin. Med. Journ.*, 1898) remarked that in association with full-time ectopic pregnancy, the menstrual function tends as a rule to re-assert itself about six weeks after the death of the fœtus, even although the dead fœtus is still harboured in the mother's body. In cases of intra-uterine death we are therefore not justified in assuming that the suspension of menstruation is simply and solely due to the presence of a perished ovum in the uterus. Again, it cannot be attributed to the mere occupation of the uterus, for this organ may contain a foreign body, like an intra-uterine stem pessary, or it may become greatly distended by retained menstrual fluid and yet menstruation recur regularly. The derangement is most probably due to some disturbance in the metabolism of the uterus, for the abortive or aberrant product of conception attracts to itself and absorbs nutriment which is elaborated and practically secreted by the endometrium. The demand made thus upon the uterus is very different to that made by an ordinary neoplasm, and induces such an alteration in its physico-chemical state generally that not only is menstruation held in abeyance, but the irritability of the organ is so impaired that it may for an indefinite time tolerate the presence of a vesicular or fleshy mole in its cavity. Reverting after this slight digression to the symptoms again, it may be observed that more or less abdominal pain is commonly complained of in conjunction with an hydatidiform mole, but this evidently is seldom noted until the hæmorrhagic discharge from the genitals attracts attention. In the diagnosis of this derangement it will be remarked that the physical signs are not specifically helpful. In the early days these may merely indicate that we have to deal with utero-gestation, and later that we are confronted with intra-uterine death. It may occasionally happen that a vesicle or even some vesicles are detected hanging from the cervical canal, and the presence of such would be considered strong corroborative evidence of the existence of an hydatidiform mole. The uterus which contains a mole of this kind may appear to be larger or smaller than the suspected duration of the pregnancy would lead us to expect; when larger the increase in size is seldom so pronounced as to constitute a sign of any real diagnostic value; but a diminished size is a most important phenomenon, since it may arouse in us a suspicion of intra-uterine death. In almost all cases of early intra-uterine death the consistence of the uterus, as estimated by a careful bimanual examination, is very different to that of a normally progressing pregnancy, and a knowledge of this may aid us in differentiating an abnormal from a normal gestation. In the case of a vesicular mole the uterine tumour is usually somewhat doughy, and no definite portions of a fœtus can be felt; ballottement is not elicitable, and auscultation reveals nothing worthy of note. The breasts occasionally, but do not commonly, display appearances indicative of pregnancy, and it seldom happens that fluid is obtainable from them.

Case I.—Hydatidiform mole as a first pregnancy at the age of forty.—Alice W., æt. 40, and married five years, has had neither a child nor a miscarriage. The last menstruation occurred three months before this patient came under my care, and during the fourteen days preceding her visit to me she had noted almost every day a little blood-coloured discharge from the vagina. During the last three weeks she had complained of pain, somewhat severe, in the lower abdomen, especially the left half.

Physical signs.—"The abdomen is occupied centrally by a small globular swelling which arises in the pelvis, and extends to a spot located

midway between the pubes and umbilicus. It is everywhere rather tender to the touch. Auscultation reveals nothing. The breasts are merely full. The cervix uteri is located far back, and towards the left side. It is rather soft. The hypogastric swelling is the enlarged uterus; its consistence is of an indescribable character, and very different to that of an ordinary pregnancy." Twenty days after the aforesaid physical signs were recorded an hydatidiform mole, chiefly composed of very small vesicles was expelled without trouble.

Case II.—Hydatidiform mole in a multipara at the age of forty-seven.—Ellen G., æt. 47, and married twenty-five years, has had ten children. She has never had a miscarriage. The last child was born ten years ago. During the six months prior to coming under my care she had noted almost daily a slight hæmorrhagic discharge from the vagina, but for five months before this started there had been complete amenorrhœa. Until eleven months ago she had menstruated as usual, and quite regularly. During the last four months she had complained more or less constantly of abdominal pain; this has never, however, been severe.

Physical signs.—"The hypogastrium is occupied by a globular swelling the size of a large cocoa-nut. It appears to be somewhat cystic. The breasts have an appearance characteristic of pregnancy, and fluid is obtainable from both, but not readily. The cervix uteri is located centrally. It is soft, and the os, which is open, has a very membranous-like margin. The vaginal roof anteriorly is slightly depressed by a swelling which is a portion of the abdominal swelling, and the whole is the enlarged uterus." Nineteen days after the aforesaid signs were noted a vesicular mole, weighing three pounds, was expelled completely and naturally.

Case III.—Hydatidiform mole in a multipara at the age of twenty-five. Conception eleven months afterwards.—Annie T., æt. 25, and married seven years, is the mother of five children. She has never had a miscarriage. The last child was born 2½ years ago, and it was suckled sixteen months. During the three months previous to coming under my care patient had noted daily an hæmorrhagic discharge from the vagina, but prior to this menstruation had been in abeyance three months. From the time that she considered herself six weeks pregnant until the constant vaginal discharge was established, she was astonished to find that sexual congress always caused her to lose a little blood from the genitals. For the last three months she had complained more or less of pain in the lower abdomen, and this had generally been worse at night. There never had been any feeling of sickness.

Physical signs.—"The lower abdomen is occupied centrally by a globular swelling, which, arising in the pelvis, extends to a spot located immediately above the umbilicus. It is everywhere tender to the touch. Auscultation reveals nothing to note. The breasts are flabby; they present none of the appearances of pregnancy, and no fluid is obtainable from them. The cervix uteri is very soft, and the abdominal swelling is the enlarged uterus."

This case I considered one of ordinary pregnancy; but two days after the aforesaid signs were recorded a vesicular mole was expelled. and the practitioner who attended her informed me that there was a good deal of hæmorrhage and that he had to clear the uterus as some vesicles were apparently incorporated with the wall of the uterus. Eleven months after this abortion the patient became pregnant again, and in due course a well-developed and living child was born.

PAROXYSMAL HEADACHE.

By JOHN T. MACLACHLAN, M.D.,
Extra-Dispensary-Physician to the Glasgow Royal Infirmary.

The author took occasion (*a*) to point out that in paroxysmal headache there were two factors that had to be attended to if success were to be obtained in the treatment of this obstinate form of recurring headache, which embittered the lives of its victims, and these were the brain and the digestive tract, particularly the liver.

The disease, in his experience, was more frequently found in women than in men. One of its most characteristic features was the regularity or periodicity of the attacks. Some patients (in bad cases) might have a daily attack; but it was more common, in his experience, for the attack to recur every week, or two weeks, or monthly.

He had cases that had a severe attack every three months, and one that was only prostrated once a year. But the last-mentioned case used to have periodical attacks every few months. The headache is of intense character, especially affecting one or both eyes, so that patients frequently cannot see to read the papers; indeed, there is a certain amount of photophobia present. In every case, except one, that had come under his observation during the last few years bilious vomiting was present, and added to the general misery.

Many of the patients were poor eaters, and several were pale and half-starved-looking. One, who was so intensely afflicted, was afraid she might commit suicide during a severe attack. The disease was closely allied to epilepsy, and the treatment he adopted, with considerable success, was similar to that employed in epilepsy.

The earliest sign of an approaching attack seemed to be the passage of a large amount of clear urine, which was probably connected with spasm of the arterioles. Throbbing of the temporal arteries could be occasionally observed. Latterly there appeared a state of congestion of the brain and liver, and probably other organs.

Two different kinds of cause were competent to determine an attack. Mental disturbance, or undue brain worry or fag would do so. On the other hand, indigestible meals, particularly when fatty or greasy articles of diet were partaken of, would start a seizure.

The principles of treatment, therefore, consisted in administering suitable sedatives to soothe the irritable brain, and to stimulate the liver; constipation, from defective secretion of bile, being generally present. He prescribed:—

R Potas. bromid., ½ oz.—6 drms.;
Potas. bicarb., ½ oz.;
Ik. aurantii, ½ oz.;
Aq., 8 oz.;
Sig.: ½ ounce after meals, in water.

and a liver pill containing vegetable laxatives, as in the well-known laxative vegetable tabloid of Messrs. Borroughs Wellcome and Co. One of them to be taken daily. When the headaches

(*a*) These remarks have been amplified before going to press.

cease to be troublesome, a course of nerve-tonics may be advantageously prescribed, especially the compound syrup of the hypophosphites. These remedies should be persevered with for a long time. The dietetic treatment was important. Most of the patients said they could not take milk or eggs. Ordinary cooked porridge soured in their stomachs. Then stews or broth were not tolerated well. There was certainly in many of those patients a faulty digestion of fats chiefly, and in a lesser degree carbohydrates. A light proteid diet was most suitable, avoiding frying as a mode of cooking. Thus, poached whites of eggs, boiled or grilled white fish, such as sole, whiting, flounder and haddock, boiled fowls, tripe, potted head, with well-baked bread and boiled rice were all suitable. Potatoes and all underground vegetables should be avoided, while tenderly-boiled green vegetables including cauliflower. were suitable and desirable additions to the dietary. Milk, which has no equal for nourishing a patient, as already stated, the patients did not find agree with them. But that difficulty was overcome by prescribing a small quantity of milk—one or two ounces—with hot water, and some bicarbonate of soda added to it. Gradually the quantity of milk could be increased until three or four tumblersful of milk were taken daily.

By the above treatment, patients were brought back to health; their headaches became tolerable and at distant intervals, and life once again became worth living.

CLINICAL RECORDS.

A CASE OF HYDATIDIFORM MOLE.

By J. MACNAUGHTON-JONES, M.D.

PATIENT, æt. 20, consulted me for metrorrhagia. She had been married eighteen months and was delivered of a still-born child at full period. She thought she had been pregnant some four months, but had a coloured discharge for some time. A few days after I saw her the hæmorrhage increased, and it was decided to empty the uterus. The mole shown * was removed, and the uterus was freely curetted, and then irrigated with weak formalin; a drain of sterilised gauze was left in and removed at the usual time.

Dr. Lockyer's report is as follows:—"This specimen shows (1) maternal decidual tissue which is very degenerate; (2) fœtal chorionic villi. The latter present marked hyperplasia of the cells of Langhan's layer, together with an abundance of syncytial buds. No large chorionic vesicles are present."

I had advised re-curettage of the womb after the next catamenial period. Seeing the nature of the pathological report, I was confirmed in the decision, and accordingly, two months after the first operation, I re-curetted the womb. Dr. Cuthbert Lockyer reported on the curettings:—"Inflammatory fibrosis has occurred in the stroma. The gland-tubules are small and show commencing atrophy. There is no sign of malignancy."

Being anxious as to the future of the case, I sent the reports to Dr. Teacher, of Glasgow, with a request for his opinion as to malignancy. He replied:—"I have examined Dr. Lockyer's slide, and I agree with him as to there being degenerated decidua and chorionic villi which show marked proliferation of the epithelium; but I would add that there is nothing in the proliferation to lead one to diagnosis of malignant disease. I have seen it quite as marked in an ovum of similar age in regard to which no such question arose. In the second place, the result of your curetting six weeks later is to my mind entirely satisfactory, and quite justifies your favourable prognosis. Moreover, the question of malignancy having arisen, whether on the clinical or pathological grounds, I think you were well advised in doing the curettement. I lately saw another chorion-epithelioma, which escaped diagnosis until too late, the symptoms having been very misleading and the onset insidious."

My object in bringing the case before the Society is to insist on the necessity of the careful examination of every suspicious mole and the prudence as a precautionary step of a subsequent curettage.

* Specimen shown and notes read before the British Gynæcological Society, July 12, 1906.

THE OUT-PATIENTS' ROOM.

HERPES AS A COMPLICATION OF A SYPHILITIC CHANCRE OF PENIS.

By HENRI DARDENNE, M.D.EDIN., M.R.C.P.

On May 6th, 1906, among the out-patients of the French Hospital was a man, named A. S., by occupation a waiter, who consulted me for some pimples on his penis and swellings in his groins. On examination I found his inguinal glands enlarged, hard and indolent. On the dorsum of the penis, in the coronal fissure, were eight or ten small erosions, the size of a pin's head, and these were capped with a muco-purulent fluid. There was a good deal of œdema about the part, this extending for about one centimetre on each side of the lesion. Palpation did not convey to the fingers the characteristic cartilaginous hardness of the syphilitic chancre. It was massive and pitted slightly on pressure. It was, in fact, diffuse. It was a typical herpetic lesion. The slightest irritation with a caustic or any irritating lotion of sores in that locality can cause a great deal of œdema and hardness. There is, I must say, never developed by these means the characteristic induration of the hard chancre, and the glands when affected are never to the same extent and in the same manner as when a syphilitic chancre is present. On further examination of the penis, I detected in the left fossa of the frænum a small circular-like excoriation about 2 millimetres in diameter, which had up to now escaped the notice of the patient and which had never caused him any pain. On dipping the index finger and thumb, and raising the ulcer from the subjacent tissues a distinct induration could be felt exactly corresponding to the base of the ulcer. It was typical of a hard chancre. There was scarcely any secretion.

Syphilitic chancres in the fossæ of the frænum are generally small and heal more or less rapidly and the induration has to be felt carefully before it is detected. These are the chancres which very often escape the notice of the patient.

The history which the man gave was briefly this. He had suffered three times from pneumonia of the left lung when he was 17, 18, and 25 years old. Previous to this he never suffered from any venereal diseases, except with a somewhat similar affection as the present one when he was 15 years old. He had had connection on April 2nd, and on May 2nd and 3rd he had felt some burning pain in the region of the glans penis, and on examination he had noticed a few white pimples about the size of a pin's head, and these on the following day had ulcerated and discharged freely. He had not noticed the small sore which was in the region of the frænum, for it had caused him no pain whatever. He could not realise that such a small sore could possibly

be the source of any future trouble, and this is generally the mental characteristic of such patients.

I advised him to use warm local boracic baths for an hour in the morning and in the evening, in order to allay the great irritation, and gave him black wash and calomel as a topical application. I prescribed mercury internally, and the salt I used was the prot. iodide in doses of ¼ grain three times daily. Under this treatment the herpetic ulcers healed within two days and the chancre within a week. The induration had nearly disappeared, and the inguinal glands had much diminished in size.

On July 6th he developed a papular syphilide which though very discrete was all the same very typical. He also had some mucous patches on the tonsils and on the mucous membrane of the lower lip, and a few papular crusts on the scalp.

Remarks by Dr. Dardenne.—This was a clear case of herpes combined with a hard chancre, and judging from the aspect of the inguinal glands the chancre had most likely appeared a few days previous to the herpes. Still more difficult cases to diagnose are those where the hard chancre and the herpes occupy the same situation. As an example of this, I may quote the case of a man who came to me a year ago suffering from herpes, and saying that a fortnight before he had had the same thing near the frænum and that it had been rapidly cured by a white powder given to him by a chemist. His glands (inguinal) were very much enlarged, and I told him that it might have been quite a different affection, perhaps a syphilitic one. Within 40 days after seeing me he developed a copious pustular syphilide. He had refused to take any mercury.

Herpetic affections of the penis are very prevalent in rheumatic individuals, and rheumatism is a very common affection in this country. No wonder, then, that patients who have had a hard chancre suffer from herpes, the chancre having acted as an irritant cause in a rheumatic constitution. It is therefore most important to be able to differentiate between the two lesions, which most often coincide or follow each other.

1. In herpes the base is not indurated, or rarely so, as when the lesions have been irritated by caustics, and even then the induration is œdematous-like in nature and is more diffuse and does not present the cartilaginous hardness of the hard chancre, which itself varies, according to the size and situation of the sores.

2. The inguinal glands in herpes are not affected, or when so they are never to the same extent as in the hard chancre.

3. Polycyclism and microcyclism, — This is one of the most important diagnostic signs. The contour of a syphilitic chancre is either circular, ovoid, or crescentic and more or less regular. On examining with a pocket lens the contour of a herpetic lesion, it is found to be irregular and geographic like in outline and this as if several segments of a minute circumference had actually fused together (polycyclism). These segments are all parts of small circles (microcyclism), like what the segments of a pin's head would be. These two signs are pathognomonic of herpes and of herpes alone. The solitary lesion of a syphilitic chancre cannot obviously enough, give the aspect of a compound one as herpes does.

4. In herpes the lesions are very small erosions, multiple, irregular, disseminated. They are also more superficial, heal more rapidly and without having any induration.

5. They are recurrent affections, the same individual being affected several times, and the patients have often suffered from gout or rheumatism. In a word, they have an arthritic constitution.

Yet with all these distinguishing features there are some cases which cannot be positively diagnosed, and time alone can help one in separating one affection from the other. As an example of the great difficulty one at times encounters, I may cite the case of Fournier, who, being puzzled as to whether a lesion was one of herpes or syphilis, sent the patient with a line to the great Ricord, who, carefully examined him for an hour and then wrote a huge interrogation point on a white sheet of paper and addressed it back to Fournier.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

TREPHINING FOR DEPRESSED FRACTURE.—Mr. PEYTON BEALE operated on a boy, æt. about 10, who had been admitted in a comatose condition after falling a distance of 12 ft. down a lift shaft. Shortly after admission the patient's state was as follows: He lay quietly in bed "curled up," that is to say, with every joint flexed, he would just open his eyes when spoken to, the surface of the body was pale, no anæsthesia or paresis, *i.e.*, there was evidence of sensation and motion on applying the point of a pin to various portions of the skin, the pulse was somewhat quickened and feeble, respirations the same, pupils somewhat contracted, *i.e.*, not dilating in the dark, right smaller than the left, temperature subnormal on admission but gradually rising. The boy had vomited three or four times. On examining the head there was obviously a depressed fracture in the right temporal region; there was a small hæmatoma over this area and extending up to the vertex; no bruising and no external wound. As the boy did not materially improve after vomiting, and as obviously depressed bone was felt through the scalp, operation was at once performed. The head having been shaved, a large flap of scalp was turned up so as to exposethe temporal region, together with parts of the frontal parietal regions. It was then seen that there was (1) a fracture starting about the region of the ear running through the temporal bone upwards parallel to the coronal suture; (2) a fracture running backwards from the temporal bone and through the right parietal as far as the occipital if not beyond it. The whole of the squamous portion of the temporal and a considerable portion of the parietal adjoining it was depressed, and was pushed under the edges of the neighbouring bone for a distance of quite a quarter of an inch. A one-inch trephine was then placed at the angle where the vertical met the horizontal fracture, so as to include part of the depressed and part of the normal bone; the latter, of course, was cut through first, and by the introduction of an elevator the depressed bone was lifted up; portions of this were cut away with bone forceps. No pulsation could be observed beneath the dura mater. On passing a probe between the bone and the dura, the latter was found to be separated over a very large area and as far upwards as the longitudinal sinus. Some blood escaped, but there was evidently no active hæmorrhage going on from any of the meningeal arteries. A small incision was then made through the dura mater, and on introducing a probe into the space between it and the pia mater about two ounces of blood escaped, all dark in colour and some in clot. Soon after this the pupils were found to be less contracted; the patient was evidently more conscious, as a greater amount of anæsthetic was found necessary to keep him quiet. A small drainage tube was inserted through the incision in the dura mater and an incision was made in the scalp flap, thus allowing the tube to project through the scalp when the latter was fixed in position by sutures. Some gauze drains were inserted beneath the scalp and round the tube between some of the sutures and in the middle

line, where a separate incision was made for that purpose. It was considered advisable to put a drain here, as it was the upper limit of the hæmatoma beneath the scalp. Mr. Beale said that the boy was clearly suffering from severe symptoms of concussion, together with those of cerebral irritation. If left alone he would have expected symptoms of compression to come on gradually within the next two or three hours. The amount of separation of dura mater was, he thought, very noticeable; it seemed as if the dura had been stripped up by blood accumulating beneath it, and yet there was not sufficient blood to account for this; it must therefore have been stripped by the sudden impact of the boy's head against some hard substance during the fall. He remarked that it was unusual for a boy to fall any distance head first; if this did occur, it resulted in a fracture of the base of the skull. The damage described in the case he had just operated on was almost certainly caused by the boy's head striking some hard substance during his fall.

ROYAL EAR HOSPITAL.

OPERATION ON A NEGLECTED MASTOID.—Mr. MACLEOD YEARSLEY operated on a youth, æt. about 15, who had been admitted on the previous day. The patient complained of great pain in the left ear and in the left side of the neck. Owing to his nationality (alien Jew) a full history could not be elicited, but it was subsequently ascertained that he had undergone a radical mastoid operation at another hospital, but, owing to his inability to attend for dressing at the stipulated time, the after-treatment had been greatly neglected. On examination a small scar was seen behind the left ear in the centre of the line of which was an opening about the size of a lentil, from which was protruding a mass of hair and cheesy material. The posterior wall of the cartilaginous meatus was so greatly bulged forwards that it obliterated the lumen of the canal. The glands in the side of the neck were swollen and the patient's head was inclined to the left shoulder. The temperature was 99 on admission, but rose on the morning of the operation to 101.5. Chloroform was administered by Mr. J. H. Chaldecott, and an incision made in the line of the scar, opening a large bony cavity filled with a foul pultaceous mass, the stench from which was overpowering; the operation was proceeded with under frequent washings with peroxide of hydrogen. It was found that the whole middle ear and mastoid formed a shell of bone full of the foul material described. The cavity in the mastoid extended to the tip of the process, where it was on the verge of perforating into the digastric fossa. The lateral sinus was exposed for about an inch; its wall was rough and apparently eroded superficially. The sinus, however, contained fluid blood. The whole cavity was thoroughly cleansed, peroxide of hydrogen being largely used for that purpose. It was further found that the previous operator had neglected to form the usual flap from the cartilaginous meatus. This omission was rectified; the walls of the fistula left by the former operation were excised and the upper part of the wound was sutured. The middle ear and the part of the cavity were packed with iodoform gauze through the meatus, but, owing to the foul condition which had been met with, drainage was also provided for through the lower part of the wound. Mr. Yearsley pointed out that this case well illustrated the evils brought about by neglect of after-treatment in mastoid cases. The ordinary radical mastoid operation, he said, provided it was properly done and every discoverable focus of disease thoroughly eradicated, usually presented no after difficulties. It was, however, of the utmost importance, he considered, that the after-treatment should be systematically and carefully carried out. Many surgeons, he said, thought to reduce the time taken up in the healing process by carrying out the subsequent grafting experiments known as "Ballance's operation," but numerous operators were inclined to abandon that method and depend upon careful plugging and antiseptic treatment. Mr. Yearsley thought that the experience of other otologists would bear him out in saying that grafting gave at least as many failures as successes; for his part he did not practise it, and yet in his operations the process of healing rarely took more than six weeks. In his opinion the results of grafting did not justify the risks incurred by one or possibly more subsequent operations. Returning to the case under consideration, it was obvious, he said, that a delay of a very few hours would have resulted in disaster. Two of the most serious complications of mastoid disease were upon the point of occurring, namely, perforation through the digastric fossa and implication of the lateral sinus. The latter blood vessel was already exposed, and its wall roughened; perforation of the digastric fossa resulted in the condition known as Bezold's mastoiditis, in which pus from the mastoid finds its way into the deep parts of the cervical region. In such cases, the counter-opening has to be made in the neck in order to drain the cervical abscess thus formed. One of the reasons for the horrible condition in which this boy's ear had been found was undoubtedly, he said, due to the omission of the previous operator to make a meatal flap. In ordinary cases a properly fashioned flap is applied to the superior wall of the central cavity, and by this means not only is the cavity provided with a source of growing epithelium, but a better communication is established with the meatus. By omitting this important step in the operation a pocket had been naturally formed between the cartilaginous meatal wall and the bony cavity in which pus and *debris* could easily accumulate.

A WORKMAN has died of bubonic plague at Havre. It seems to have been an isolated case, and although it is not stated where he caught the disease, there have been no further attacks. It should be remembered that, whatever may be the case in other European States, the medical and police regulations in France and Germany are so stringent that there can be practically no danger of disease spreading to England.

THE foundation stone-laying ceremony in connection with the new Central Home attached to that splendid institution, the Birmingham Lying-in Charity, Loveday-street, immediately to the rear of the Birmingham General Hospital, was performed by Mrs. C. G. Beale, wife of Alderman Beale, on July 14th.

DR. JAMES STEWART, of Rickmansworth, whose death we recently announced, has left estate in the United Kingdom valued at £135,604 8s. 9d., with net personalty £134,043 10s. 4d. He left two-tenths of his estate (over £25,000) to the University of Melbourne, Victoria, for scholarships in anatomy, medicine, and surgery.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 12th, 1906.

MR. BOWREMAN JESSETT, President, in the Chair.

DR. JERVOIS AARONS showed a modified hollow ring pessary filled with a mixture of gelatin and glycerin, which made it pliable and when in use became still more so. The central opening was very narrow. He devised this pessary four years ago, for two patients who had acute retroflexion with prolapsed ovaries, as none of the pessaries he tried gave relief. While wearing the pessaries the symptoms disappeared completely.

The PRESIDENT asked whether it was used for retroflexion or prolapsed ovary. He would also like to know whether Dr. Aarons had tried a pessary with a soft pad on the posterior limb. He (the President) had found this form of pessary very useful in retroversion, and the pad seemed to keep the fundus of the uterus in its place, which he would have thought the present one would not.

Dr. HEYWOOD SMITH considered the weight of the pessary a disadvantage. The central aperture was too small for the cervix to pass through, so that the uterus would ride higher, and in some cases prevent the replacement being maintained.

Dr. SMALLWOOD SAVAGE asked whether these pessaries were used in uncomplicated cases only, and also if the condition was cured by using this pessary.

Dr. AARONS, in reply, said he had used the pessary for four years. The patients never complained of the weight of the pessary. It was only where the cervix was small that the pessary was useful. He had tried the pessary mentioned by the President, but it had not given any relief. A pessary seldom cured retroflexion; it more often only relieved the symptoms. The pessaries had been used in married women only.

Dr. CHARLES MAUNSELL showed a series of specimens (1) The first, carcinoma of the cervix, removed by Wertheim's operation. The specimen comprised the uterus with the broad ligaments, ovaries, tubes and the upper third of the vagina, with the para-vaginal and para-cervical tissue removed in one mass. After removing the uterus he dissected out the glands from the pelvis, and as they were enlarged along the iliac vessels he followed them up as far as the kidney on each side. That course did not add more than a few minutes to the operation, as the glands were very easily found. He found the ureter readily by tilting forward the ovary out of the ovarian fossa, when the ureter appeared through the peritoneum and was easily reached. Though the glands were so enlarged he could not find any evidence of cancer in them. His patient had no leakage of urine until the tenth day. On the tenth day urine was passed by the vagina through a fistula, but by washing the bladder out regularly it healed up in a few weeks.

(2) The second specimen was one of carcinoma of the ovary removed from a girl, æt. 25, who complained of a swelling in her abdomen for five months. She was a thin girl, and one could distinctly feel and see the tumour in the right iliac fossa extending towards the middle line. When he opened the abdomen there was some ascites present; there were adhesions between the tumour and surrounding structures; also between the liver and the abdominal wall. As he did not consider the growth malignant, he did not remove the other ovary. He removed a small cyst from the left ovary, which was innocent. However, the patient is still under observation and examined every few months. Though she was operated upon in March, 1906, she had put on flesh and there had been no recurrence.

(3) The third specimen was a myoma of the cervix in a woman æt. 47. She had metrorrhagia severely for two years. She had spoken of it to her neighbours and had been told by them it was usual for women approaching the change of life to bleed like that. She was practically bloodless. On examination, a tumour was found attached to the cervix which bled profusely when touched, so that he had to plug the vagina and did not examine it again until he was ready to operate. On drawing the tumour out of the vagina he found it was held by a narrow pedicle, which he snipped through with scissors. There was no further hæmorrhage and the patient recovered.

(4) The next specimen was one of tubo-ovarian abscess, and salpingitis of the other side. The patient was a multipara, æt. 24. He removed the tumour on May 6th, 1905. She was well for some months, and then complained of a profuse discharge from the vagina, with great pain which began after January 1906. He then removed the uterus, which was in a state of chronic metritis with profuse suppuration. He desired to raise the question whether he ought not to have taken away the uterus when he removed the tubes. It became necessary to put her under a second operation before she was cured.

(5) The next specimen consisted of two large tubo-ovarian abscesses of gonorrhœal origin, which had burst, and there was general peritonitis. The patient was a young woman, æt. 23, married about one year. She had no children, and complained of discharge from the vagina and some pain in the pelvic region. Three days previously she was seized with violent pain in the abdomen, and before that she was supposed to be suffering from influenza. On the day he saw her she had an attack of severe pain. She was sent up by train a distance of some forty miles and on arrival she was collapsed. A provisional diagnosis was made of ruptured pelvic abscess. On opening the abdomen he found free pus and two tubo-ovarian abscesses. He made two incisions, one below the umbilicus, and one above, washed out the abdomen, and drained with gauze. She made an uninterrupted recovery, and to-day was well and healthy.

(6) The last specimens were two tubo-ovarian abscesses which had ruptured two days previously. He operated as in the former case, but the patient died a few days afterwards. He did not regard the abscesses as gonorrhœal.

Dr. MACAN asked whether, in the second case of tubo-ovarian abscess, there was general peritonitis, and if so how long had it existed, and what was the cause of death?

Dr. HEYWOOD SMITH asked, in regard to the case in which the uterus was subsequently removed because of purulent endometritis, whether the interior of the uterus was examined at the time of the first operation, and whether it would not have been better to have postponed the operation until the inflammatory condition had subsided. By doing so it was possible the uterus might have been saved.

Dr. HODGSON asked what means had been taken to prevent infection after removal of the myoma of cervix? He would like to know whether antiseptics had been applied to the stump.

Dr. MANSELL MOULLIN said it was most unusual for pyosalpinx to rupture. He had operated on many cases, and had seen many more, but had never come

across a case which ruptured spontaneously. The interesting point about the series of specimens was that there should have been two cases which ruptured spontaneously.

Dr. SWANTON said the suggestion as to the means of recognising the ureters was valuable. With regard to the question of draining, Dr. Maunsell said he made the opening above the umbilicus as well as the one below. He considered it would have been better to have made an opening in the flank and drain through.

Mr. HARRY OVERY said he had noticed in several cases that the leucocyte count was a valuable aid as to the condition of the tubes, that is to say whether pus formation was taking place. He had seen two *post mortems* in which general peritonitis followed the rupture of pyosalpinx during operation.

The PRESIDENT asked how long it took Dr. Maunsell to remove the uterus and the glands in the abdomen, also what determined his choice of the route he employed in preference to doing a vaginal hysterectomy. Looking at the specimen, it appeared to him (the President) to be one which might easily have been removed by the vagina. The disease seemed fairly limited, the os and uterus were mobile and could have been readily drawn down. Time was an element of great importance in those operations, and removal by the vaginal route could have been accomplished in from thirty to forty minutes. He would be glad to hear how long the operation occupied Dr. Maunsell. Another question was the urinary leakage which resulted. Was it from sloughing of the bladder or from damage to the ureter? He had done Wertheim's operation three times. In one case which he had described already, the ureter was surrounded by the disease, and in removing the disease he tore the ureter across. The patient lived, but had a uretero-vaginal fistula. Dr. Maunsell's plan for finding the ureters was a valuable one. The chief difficulty was tracing the ureters down into the bladder so as to push them away from the uterine tissues. The case in which there was rupture of the tube was a very interesting one. He had never seen a case in which a tube had ruptured spontaneously, but he had seen several cases of pyosalpinges, in which while removing the diseased tubes the tubes had broken down and burst into the peritoneum. As a rule very little injurious result followed. Personally, he objected to washing out the abdomen in such cases, for it dispersed the pus.

Dr. MAUNSELL, in reply to Dr. Macan, said that in the first case there seemed to be a double rupture. The first one occurred several days before he saw her, as she had very severe pain. On the day patient was seen by him (Dr. Maunsell) she had another severe attack of pain. It seemed to him at first that there had been some leakage and the formation of an abscess with adhesions and that the abscess secondarily ruptured the day she was seen by him. Immediately the peritoneum was opened pus welled up. In reply to Dr. Heywood Smith, no medication could have possibly cured that tubo-ovarian abscess. A microscopical examination had been made of the ovarian tumour. As to the use of antiseptics in the case of cervical myoma, he douched the vagina before removing it, and the only after treatment he adopted was plugging with iodoform gauze, which was left in for forty-eight hours. The patient had not had a bad symptom and was up in a few days. The President desired to know how long Wertheim's operation took him. Including stitching up the wound, the time occupied was a little short of two hours. In the first case of tubal abscess the diagnosis of ruptured pelvic abscess was made. In the second case his diagnosis had been ruptured appendix. The carcinoma of the ovary was primary, and the pathologist confirmed that view. The adhesions did not seem to have anything to do with the cancer, there was no enlargement of the liver, and the adhesions were fairly soft, he could not understand how the peritonitis had been caused. The girl had since put on weight immensely and looked and felt well. Mr. Overy's question was concerned with the leucocyte count. In neither of those cases had he (Dr. Maunsell) time for that. The President asked why he chose the abdominal route, and stated that the operation performed was not really Wertheim's. The operation he (Dr. Maunsell) performed was, according to the opinion of the Master of the Rotunda, who saw the operation, Wertheim's, and a complete one. He did not think there was much more cellular tissue in the pelvis than was present in that specimen. With regard to the choice of route, of course it was easy to be wise after the event, and as it turned out it would have been possible to remove that fairly well by the vaginal route, though when he saw the case and examined it, the carcinoma was spreading out from the cervix on to the vault of the vagina. It was more extensive-looking than appeared from the specimen shown. He certainly believed it was better to remove every case of cancer of the uterus by the suprapubic route. With regard to the urinary leakage which occurred in one case, he thought it fairly certain that it was from some sloughing of the bladder.

Dr. HEYWOOD SMITH said, in explanation, that Dr. Maunsell appeared to have slightly misunderstood his question. He (Dr. Smith) did not suppose that any treatment could have influenced the ovarian disease if both ovaries were in a suppurative condition.

Dr. MACNAUGHTON-JONES showed a specimen of "Hydatidiform Mole," and read the notes, which are published elsewhere in the present issue (see page 88).

Dr. JAMES OLIVER read a paper on "A Study of Hydatidiform Mole, with the records of three typical cases," which will be found elsewhere (see page 85.)

Dr. HEYWOOD SMITH asked whether Dr. Oliver did not think it possible that the degeneration of the chorionic villi began at an earlier period than he seemed to suggest. He thought it would be advisable to refer Dr. Macnaughton-Jones's specimen to a pathological committee, as it did not seem to possess the characteristics which one generally associated with hydatidiform mole. There seemed to be an enormous hypertrophy of endometrium, and perhaps under those conditions curettage was justifiable. The tissue removed seemed to be somewhat fragmentary. In the case of an ordinary vesicular mole there would be no justification in subjecting the patient to the extra risk of a subsequent curettage at all. It was very unusual, in his experience, to see a hydatidiform mole thrown out at such an early stage as in the present case. It was only a couple or three inches long. As Dr. Oliver had shown, those moles grew, and not until the mole became so large as to act like a foreign body did the uterus make an effort at expelling it.

Dr. AARONS asked what was the subsequent history of those cases which were mentioned by Dr. Oliver?

Dr. OLIVER said one might have natural conception afterwards, and that seemed to negative the necessity for curetting indiscriminately. Of course, according to the pathology of chorionic epithelioma, it would seem as if hydatidiform moles had a disposition to embed themselves in the uterus, and the question was whether mere curettage would be sufficient in view of the possibility of the cases becoming malignant later on.

Mr. SMALLWOOD SAVAGE said his reason for rising to speak was that he had had two cases of hydatidiform mole, which occurred at the end of the child-bearing period, and one would think it was due to some reduced resistance of the maternal tissue to the chorionic epithelium. With regard to the pathology of the condition, it would have been interesting to have heard from Dr. Oliver if the sections had shown an excess of Langhan's cells. He would have liked to have heard what Dr. Oliver thought of the pathological examination of those tumours. Personally, in spite of the microscopical examination, he (Mr. Savage) would not regard that as of any great value. He considered that the clinical symptoms were everything to go by, and that if any hæmorrhage occurred after the first curettage, vaginal hysterectomy should be performed. He thought Dr. Oliver was rather lucky in his cases, when one remembered how the hydati-

diform moles in his own cases ended. With regard to pain, he would not agree with the view mentioned by Dr. Swanton, that pain was caused by the growth of the chorionic villi extending on to the peritoneal surface. In destructive hydatidiform mole many cases had been described where the mole had extended on to the peritoneal surface, and the patients had probably died very soon afterwards. But probably one of the symptoms in a large hydatidiform mole in the uterus was pain, and that was due to the extending of the uterus into the surrounding regions.

Dr. HODGSON asked whether it was absolutely necessary that a woman should conceive in order to have those vesicular moles. He thought it possible that a woman had an unhealthy lining to her uterus, and at the time she conceived the tissue was excited by conception and the mole was either stimulated to grow or was cast off. He did not think it had been clearly established that conception was absolutely necessary as a condition for having those moles.

Dr. OLIVER, in reply to Dr. Heywood Smith, said he did not think it was possible to have any change in the villi earlier than the third week. In his paper he stated that the change most likely occurred between the third and the sixth week. He had no doubt that the condition was inherent in the oosperm, immediately the spermatozoon and the ovum coalesced. Immediately fecundation took place there was no doubt a tendency to produce a mole. But he did not think it was possible to detect the change until the vessels from the allantois thrust themselves into the villi, until the ovum was placental all over. In reply to Dr. Aarons, he said it was remarkable that the only case which had come under his notice in which there had been any trouble in removing hydatid mole was the one in which the patient became pregnant eleven months afterwards. In all the other cases which he had seen, the mole had been expelled easily, without trouble and there had been no adhesion to the uterine wall anywhere. But in that one to which he had referred the patient was æt. 25, and had had five children before becoming pregnant eleven months afterwards. The medical men who had had the cases under their care after he had seen them had written to say that there was no trouble, except in that particular case, and in that the medical attendant said he had emptied the uterus with his hand, and had to scrape the mole from the uterine wall. In answer to Dr. Swanton it was of course admitted that those cases were much more likely to give rise to a malignant condition than were others, but it seemed to him that there was no difference in the moles themselves. It was simply a question of degree. The morbid process extended through the uterine wall, and this established the condition of malignancy, just as in adenomatous degeneration of the lining of the uterus one got some cases in which the adenomatous growths tended to penetrate the wall of the uterus. It was in such the extent to which the uterine wall was invaded which constituted the malignancy, and it was the same with hydatid moles. Dr. Swanton drew attention to the question of pain. He (Dr. Oliver) could not explain the pain at all. Pain in those cases had always been a great enigma to him, because one found exactly the same kind of pain in early uterine death, where the ovum had perished at the sixth week, and yet was retained five, six, or ten months. In these cases there was more or less abdominal pain. He could not say that the abdominal pain was due to the attempt on the part of the uterus to expel the mole. With regard to age, it was true the condition appeared to be more common towards the end of the reproductive life of the woman. But one found it almost as commonly under 35 years of age. About three months ago he saw the condition in a woman æt. 24, who had been married only 18 months. With regard to Dr. Savage's case in which there was no amenorrhœa, it was difficult to understand how one could have a hydatid mole with no amenorrhœa at all, because the hæmorrhage undoubtedly came from the uterine vessels and there was not much enlargement of uterine vessels until the sixth week, that is until the chorionic villi began to irritate the uterine wall to such an extent that the vessels responded. It was very difficult to understand why there should be no amenorrhœa. He did not believe in the differentiation of moles at all; he believed all moles were very much alike; it was the question of the incorporation of the embryonic with the maternal tissues which constituted the malignant tendency. Microscopically there seemed to be no difference in them. Of course those which penetrated the uterine wall a little more deeply seemed to show a little cell infiltration, but that was merely an exaggerated condition, an exaggeration of the more simple condition. With regard to Dr. Hodgson's question about single women, he did not think it was possible for a hydatid mole to occur in a woman who had never had sexual intercourse, the mole was due to the fertilisation of the germ plasm, undoubtedly.

GERMANY.

Berlin, July 22nd, 1906.

The *Zeitschrift fur Hygiene* 50-3 contains a paper on EXPERIMENTAL BACILLARY PNEUMONIA by Dr. J. Kokawa. Experiments made by the author led to the conclusion that the disease is set up by direct injection of the bacilli into the lungs, or the infection may pass by the air passages. Probably in the human subject the infection is usually brought about in the latter way. But a hæmatogenous infection is not excluded, as the excitors of the disease may readily pass by the blood channel from some primary centre of disease.

The encapsuled bacilli alone are only capable of setting up disease when they are very virulent or are in large quantities; otherwise, predisposing conditions are necessary, such as injury, or a chill, etc. These factors apparently play an important part in the bacillary pneumonia of man, as here the bacilli do not penetrate in such large quantities as in experiments on animals.

Bacilli in whatever way they are brought into the lungs, are admitted through the epithelium of the alveoli into the lymph channels. Through the lymph systems of the lobar and alveola septa they spread out into the whole organ. The bacilli so taken up, for the most part, die so long as the lung tissue is sound. Inflammations of the lungs are only set up when the bacilli, unusually virulent, are eliminated into the alveolar lumina. The bacilli are much more quickly taken up into the lymphatic system as charcoal pigment. The reason for this is perhaps partly the chemotactic action of the bacilli on leucocytes.

The histological changes of experimental bacillary pneumonia and pleuritis are characterised by features that have a close connection with the biological properties of the capsule bacilli. *i.e.*—by a relative copiousness of mucus and strong swelling of the vacuole structure of the cellular elements in the exudate.

The passage of bacilli, into the lung tissue through the wall of a bronchial tube has not been proved.

AUSTRIA.

Vienna, July 22nd 1906.

CARCINOMA AND THE RONTGEN RAYS.

RIEHL showed the members of the "K. K. Gesellschaft" two microscopic preparations that raised an important discussion on the Rontgen rays producing carcinoma.

The first specimen was an epithelial carcinoma arising from the epidermal layer, while the second specimen was a spindle-shaped sarcoma. Both of these

neoplasms were taken from the cheek only two centimetres apart: the former from the superficial layer, the latter from the deeper cutis; both had risen from the cicatrix of Rontgen ray burns which had been applied for lupus seven centimetres broad, eight years ago. Ulceration was produced by the rays which caused a telangiectasis to appear that extended from the eyelid to the mammilla. It cured the lupus at the time, but a new area of lupus appeared later in a different place. The two tumours shown had no constituent of lupus although they originated on the cicatrix of the original lupus.

He showed another case of lupus vulgaris, which involved the whole side of the neck and head as well as a third of the thorax.

On the right side of the neck was a carcinomatous tumour ten centimetres, movable and lupus infiltrated at the base.

The patient had been frequently treated with the rays without effect.

Ehrmann asked how he could eliminate a Lupo-epithelioma which frequently did occur, quite spontaneously in lupoid cases. He would not venture to contradict Riehl, but thought there was a great doubt in the matter.

Holzknecht questioned the correctness of carcinoma arising out of the ulceration from rays. According to Unna's experiments there is a possibility of such arising, but there is also a possibility of some of the neoplasmic cells remaining after the ulceration from the rays.

There is no testimony to prove in the neoplasms shown, nor is there any proof in the surrounding tissues that the Rontgen rays had effected; and if no transformation can be proved, how can we say the rays produced cancer? Again, we have no history of the amount of ray force applied, and as we have carcinoma arising out of lupus it is just possible the quantity of rays was too insignificant to destroy all the lupoid cells though it may have arrested their progress.

Nobl said the Rontgen rays have the power of producing an atypical epithelial growth not unlike that produced. It is also observed that small doses of the rays produce various complex reactions such as the form of xerodema pigmentosa of Kaposi which has a decided tendency to become carcinomatous.

INTRA LIGAMENTAL PREGNANCY.

Lindinthal exhibited a patient he had successfully operated on for a pregnancy that took place in the meso-salpinx and rectum. The diagnosis was intra-uterine pregnancy with ovarial cyst, as the tumour lay to the left side with the symptoms of pregnancy.

When the laparotomy was performed the uterus was found empty of a fœtus; but there was present great hypertrophy and a decidua 8 millimetres thick, with a fœtus in the mesorectal ligament 22 centimetres in length. There was no ovarian cyst present.

THYROID CELLS.

Konigstein demonstrated the different secreting powers of the epithelial cells in the thyroid gland. There are two different forms in the parenchyma of the gland, (*a*) the large polygnal cell with well defined walls that takes up eosin greedily; (*b*) the small shrunken cell that takes up the colouring matter very sparingly in masses and not diffused as in the polygnal. The large cells are found individually throughout the gland intensely coloured, at other times in groups which are usually near the periphery and mostly to be met with in adults. In many places these polygnal cells form follicules by their arrangement with lumen in which a small drop of the eosin may be seen secreted from the cells.

ELEPHANTIASIS LYMPHANGIECTODES.

Lehndorff showed a child 16 months, with elephantiasis cong. præputium. After a normal birth a painless swelling was observed over the genitals and penis; no tumour, no swelling at the inguinals, nor enlargement of vessels.

HUNGARY.

Budapest, July 22nd, 1906.

SURGICAL CUTFIT FOR FIRE COMPANIES.

TWENTY-FIVE leather cases, containing emergency medicines and surgical instruments, are to be furnished to every company in the Fire Department of Budapest. With these cases always available, any one with surgical knowledge present at a fire may treat wounds on the spot. It is possible, too, that instruction in first aid to the injured will soon be given to all firemen.

SUICIDE BY CARBOLIC ACID.

The use of carbolic acid is not a passing fad among suicides. It is an established custom, due primarily to the fact that the legitimate uses of the acid are so numerous that it is easy for almost any person to give a druggist a plausible reason for the purchase. Death by carbolic acid is death by torture, but the would-be-suicide who is in real earnest does not stop to bother himself about a few moments or a few hours of agony. The Apothecaries' Association here favours the passage of a new ordinance regulating the sale of poison, and the Council will do well to give the proposal careful consideration. It is said that the placing of restrictions upon the free sale of concentrated solutions will do much good, with little inconvenience to the public, inasmuch as the more diluted solutions are perfectly satisfactory for most legitimate uses. The concentrated solutions are fatal but the weaker solutions are much less dangerous. There is reason to believe that a properly framed ordinance would reduce the number of suicides.

In an able article on the

TREATMENT OF GASTRIC ULCER

Dr. Wagner says that it has been customary to keep patients on a milk diet at least four weeks, after a hæmorrhage from a gastric ulcer and to avoid all other, especially proteid foods. This, he thinks, is a mistake. He has often observed the good effects of proteids in the hyperacidity of chlorotic girls without ulcer, and was led to try the same diet in ulcer, arguing that albumen binds the free hydrochloric acid, which keeps up the irritation better than any other food. The patients are often in a condition of chronic inanition; to begin with rectal enemata and small amounts of milk would be to keep up the starvation and thus prolong the healing of the ulcer, while large quantities of milk sufficient to meet the demands of the system would be risky. The treatment as practised by the author is as follows: Absolute rest for at least four weeks, icebag to the epigastrium. On the day of hæmorrhage 200 to 300 ccm. of iced milk and 1-3 fresh raw eggs are given, together with two grams of bismuth three times a day. By the end of the first week, the milk has been increased to 800 ccm. and the eggs to six to eight a day. Raw, scraped meat is allowed after the sixth day and after two weeks boiled rice or farina and zwieback. In three to four weeks a carefully selected mixed diet is well borne. The amount of bismuth is reduced considerably after ten days and at the same time iron in the form of Blaud's pills or with arsenic is begun. As compared with the milk diet, recurrent hæmorrhages are less frequent and the gastric pains are alleviated more readily and the general condition improves quickly. A large number of the patients were again seen a year after the treatment; the majority had experienced no further trouble.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

ADDRESS AND PRESENTATION TO DR. DARNELL.—At a meeting held in the Medical Institute, Belfast, on the evening of the 17th inst., Dr. C. K. Darnell, of Bangor, co. Down, was the recipient of an address, a presentation of silver plate and a cheque for three hundred guineas from a large number of his medical brethren. On the motion of Prof. Symington the

chair was taken by Dr. J. Walton Browne, and letters of apology were read by Dr. Houston from the following:—Sir Wm. Whitla, Prof. Byers, Dr. Jefferson (Lisburn), Dr. Killen (Larne), Dr. Rowan (Gargary, co. Down), Dr. Warnock (Donegal), Dr. H. Buchanan Murray, Dr. Chas, C. Cathcart, Dr. J. S. Morrow, and Dr. Joseph Nelson (Belfast).—The Chairman briefly alluded to the circumstances which led to their meeting that evening, and spoke of the trying time through which Dr. Darnell had passed, and the universal sympathy felt for him by his medical brethren. Now this trouble was ended he hoped many happy years were in store for him and Mrs. Darnell. He then called upon Dr. Wm. Calwell, President of the Ulster Medical Society, who conveyed to Dr. Darnell the deep and warm sympathy, not only of the members of his Society, but also of numerous medical men throughout the United Kingdom who had joined in the presentation. In his capacity as one of the treasurers of the fund he had received letters from all quarters expressing hearty sympathy with Dr. Darnell, and often the wish that the case could be fought further. He claimed for Dr. Darnell that he had "exercised a reasonable degree of care and skill," also honesty of purpose and uprightness of conduct, which seemed to his professional brethren to entitle him to a verdict. It was only the absolutely prohibitive expense that prevented the case from being carried to the House of Lords.—Dr. Cecil Shaw, Hon. Sec. of the Ulster Branch of the British Medical Association, also read an address to Dr. Darnell, expressive of sympathy in the anxious and harassing experiences through which he had recently passed, and as a token of the friendship and sympathy of its members, they begged his acceptance of the accompanying cheque and piece of plate. The Chairman then handed to Dr. Darnell with the address a pair of solid silver candelabra, and a cheque for three hundred guineas, to which Dr. Darnell replied as follows:—"Mr. Chairman and Gentlemen,—Your truly kind address and generous presentation have been to me a matter of deep personal and professional satisfaction. It is particularly gratifying to me to know that you have recognised the justice of my contention in the recent prolonged lawsuit. I cannot imagine a more satisfactory or decisive pronouncement on a subject which touches the reputation of a brother than this professional assurance of yours. To enjoy the confidence and esteem of my patients and friends is to me a most pleasing reflection, and to receive the endorsement of their good opinion by my professional brethren is an honour and a privilege of which I may well feel justly proud." To the formal reply Dr. Darnell added a few words of thanks, not only for the substantial help that had been given him that evening, but also for the great kindness and sympathy he had received during the past two years, and without which he felt he could hardly have got through that time. On the motion of Dr. John Campbell, a vote of thanks was passed to the Chairman, and the meeting terminated.

COUNTY ANTRIM INFIRMARY.—The annual report of this institution, just issued shows an increase of work and a decrease of funds. The patients treated in the wards numbered 338, with a daily average of 33·74. The annual expenditure per patient for food was £11 12s. 10d., and for drugs and dressings £4 17s. 7d. The operations performed numbered 118, and the accidents treated were 293. Dr. St. George gives the record of an excellent year's work.

UNSOUND PORK.—Apparently the Chicago scandals have stirred up our local authorities to renewed vigour in the inspection of meat, a very desirable result. Last week the carcases of six pigs were seized and condemned as unfit for food, owing to tubercular deposits. It turned out that they came from the Downpatrick Asylum, and the authorities there, while giving every assistance at the inquiry, said that they slaughtered about one hundred pigs annually, and these were the first ever condemned, or even complained of. Some discussion took place in the Magistrates' Court on the appearances which would lead to an order for the destruction of the carcases. In these cases the disease appeared only in the necks, while the viscera appeared to be quite healthy. The presiding Magistrate said he knew it was a disputed point, but he did not intend to experiment on the inhabitants of Belfast, and ordered the destruction of the doubtful carcases.

INFANTILE MORTALITY: ADDRESS BY PROFESSOR BYERS.—At the annual meeting of the Bangor Nursing Society, held last week, an address on Infantile Mortality was delivered by Prof. Byers. After some general observations and some statistics, showing the importance of the subject Dr. Byers pointed out that as a whole infantile mortality had remained stationary of late years, while the death-rate generally had declined. From observations on those in a fair state of comfort and of intelligence, we might conclude that the normal rate for infants under one year old should be about 75 per 1,000, though from what is occurring in France, where great attention is being devoted to the subject, we may consider even that too high. There was no difficulty in showing that the question was essentially one of feeding. The lecturer put this in various ways, but perhaps the most striking to his lay audience was the observation of Newsholme, that it was twice as dangerous to feed an infant on condensed milk as on fresh cows' milk, fifty times as dangerous to feed an infant on cows' milk as on breast milk, and one hundred times more dangerous to feed it on condensed milk than on breast milk. Various schemes for educating and helping the mothers were described, and their results given, Huddersfield and Glasgow being specially recommended.

COUNTY ANTRIM ASSIZES: GRAND JURY.—No less than five medical men have been summoned to the Grand Jury at the present Assizes in Belfast. They are Drs. O'Neill, Dempsey, McKisack, Kirk, and Williamson. Happily for them, they are not likely to have to devote much time to their duties this sitting, as the calendar is a light one.

LETTERS TO THE EDITOR.

THE CHRISTIAN SCIENCE TRIAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This case having terminated in what lawyers call a *nolle prosequi*, and your correspondent "Common Law" having kindly favoured us with an exposition of the law as far as it is definite on the question, perhaps you will allow me a statement that I was restrained from offering in my previous letter. It appears to me that some confusion has arisen in the public mind from which lawyers have not altogether escaped infection, otherwise the case would not have proceeded beyond the inquest, and that is that the public have come to regard "Christian Science" as though it were a form of quackery in medicine, whereas on the contrary it is simply as "Common Law" points out a religious ceremony or rite. There is, of course, nothing illegal in the exercise of such rite, consequently Dr. Adcock, I presume would not be responsible for not providing the deceased with legal medical attendance and having done nothing to accelerate death could not be liable in criminal law. In one word he has been in the position of a person falsely charged of committing a crime.

The confusion to which I refer, I should say, arises from the adoption of the absurd name of "Christian Science," which has not unnaturally generated the idea that something appertaining to the charlatan's treatment of disease is necessarily involved, but this is not the case, and so far from being so the defendant was taunted by counsel for departing from his recognised tenets and applying an antiseptic dressing, but I do not think counsel could make much of this, it being an ordinary precaution of cleanliness and such an one as any person might adopt where no sickness was concerned, as for instance, in spraying a room with Sanitas or Condy's Fluid, in order to freshen the atmosphere.

A second case of re-trial having just been recorded in another instance of death, the jury disagreeing, fills

one with confidence in this regard; it shows that the difficulty a jury sometimes experiences in decision, warrants the inference that every care is taken to sift the evidence—and to deal justly with all.

I am, Sir, yours truly,
CLEMENT H. SERS.

Brighton, July 20th, 1906.

SHODDY LEARNED TITLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter from "Ethics" in your issue of July 18th is calculated to make us blush for our profession. When your original annotation told us that certain ambulance students had affixed the letters M.B., B.A., after their names on the strength of some grotesque denotation of their membership of St. John Ambulance Association, one was moved to contemptuous amusement at the inherent snobbishness of mankind. But now it appears from "Ethics'" letter, that the offender was a qualified medical man. That is another matter. We are entitled to demand investigation of the matter by the Defence Societies and by the General Medical Council. The latter body has shown itself in times past keen enough to prosecute medical men for using reputable American degrees to which they were legally entitled. What has the Council to say now to a medical man who deliberately misleads the public by an absolutely false suggestion that he is entitled to the degrees of M.B., B.A.?

Let us hope, Sir, for the honour of our profession, that there is some mistake somewhere, and that no medical *confrere* could have stooped to so discreditable an act. From your correspondent's letter I see that the tricky letters F.R.G.S. are said to have been also added. If there be one inexcusably mean thing more than another it is to add the letters F.R.G.S. to a medical title, when it is clear that the public must inevitably confuse them with F.R.C.S. Any self-respecting medical man would avoid using the title as he would shun the devil—unless, indeed, he happened to be in fact a distinguished geographer, which the majority of those holding the Royal Geographical Society's fellowship are probably not.

What have the St. John Ambulance authorities to say.?

I am, Sir, yours truly.
Clapham, July 20th, 1906. F.R.C.S.

SPECIAL ARTICLES.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

REPLYING to the Medical Deputation which waited upon him on July 16th, to urge the necessity of systematic inspection of school children, the Minister of Education gave little hope that provision for this could be included in the new Education Act; but it is gratifying to note that in the debate upon the bill on the same evening expressions of opinion from all sides of the House were so unanimous and emphatic that the Government in the end agreed to amend the Act by addition of the following Clause: "It shall be the duty of every local authority to provide for the medical inspection of every child on its application for admission to a public elementary school, and on such other occasions as the Board of Education may direct, or the local education authority may think fit." In view of the fact that this addition to the Act, although it will no doubt disclose the amount of existing illness and physical disability, will make no provision for treatment of delicate children, it is difficult to understand the optimistic expression of opinion which Mr. Birrell put forth to the deputation, even before the amendment afterwards agreed upon had been proposed, He said that in this matter we should soon have caught up any foreign country and in future we should lead the way. He gave not the least hint as to the means, methods or machinery by which this desirable consummation was to be brought about, nor did he throw any light whatever upon it in his speeches later in the House of Commons. Certainly at present they manage these things so very much better in Germany that we shall at first, whatever energy be displayed be conducting the proverbial stern chase, which is always a long one. Not only have they in Germany for years practised the most systematic and complete inspection of school children, but they have organised the ways and means of dealing with the cases which call for medical supervision and treatment. In the matter of the physical development of the children, in every fundamental question touching the public health, in all the practical details of sanitary administration throughout, the Germans are advancing if not by leaps and bounds at least steadily and with sure footsteps to the front. Germany is presenting an elaborate object lesson in the fact that a bureaucracy of first-rate quality, guided from the centre by the best scientific advice and directing a well-educated and therefore in such matters a docile people can produce results much better than is possible with free democratic local governing bodies such as we rely upon in this country. Such bodies can act with wisdom only when made up of a fair proportion of what is wisest and best among the citizens; when dominated by what is most ignorant and most selfish the results, if not farcical, are too often tragic. Of this latter fact the last illustration was afforded by the exposure of the working of the now superseded Merthyr Tydvil Urban Council of which we lately gave an account. This Council had the reputation of being the worst in the three kingdoms; but many more sanitary authorities occupy positions not much below that bad eminence. Medical officers of health and sanitary inspectors are the servants of the local authority and in most cases are absolutely powerless to do more than carry out the orders of their masters without protest or complaint. This will be the position of medical school inspectors if such be appointed, for be it remembered that even medical officers are at present not employed by large numbers of authorities. In Germany not only have they practically banished small-pox by enforcement of vaccination and re-vaccination, which are ensured by surveillance of school children, but they are checking measles and scarlet fever and are raising the standard of health all along the line by attention to minor ailments and disabilities. Ears, eyes, and throats are systematically examined and children with defects in these regions are, when necessary, classed apart and separately dealt with. Dull and backward children, those of low intellectual capacity are also specially considered. Directly and indirectly in the matters of clothing and cleanliness much is effected; bathing by means of inexpensive douching and soaping is now practised at most schools, whilst hair is kept short and heads kept clean; and no one thinks of resenting the regulation by authority of such small but important items which contributes towards the welfare of the whole community. Here at home our people largely prefer to remain free and dirty, and our working classes are certainly among the least well tubbed in Europe. They have not been taught like the Germans to wash their bodies while young, and find it impossible to acquire a taste for personal ablutions in after life. All our public baths, however cheap and accessible, are failures as regards the great mass of the poorer classes; and as these classes have no facilities for bathing in their crowded homes, it is obvious they must in the main go unwashed.

THE MANAGEMENT AND CONTROL OF LUNATIC ASYLUMS IN IRELAND.

FOR some time past the medical profession and the general public have been interested in a dispute which has raged between the committees of various lunatic asylums throughout Ireland and the Local Government Board with reference to an Order issued by the

latter body and known as the "Public Bodies Order." In this dispute, the superintendents of the Asylums for some time sided with their respective committees, because it appeared that in various particulars the Local Government Board were striving to cast unnecessary duties of an absurd and onerous nature on the superintendents, and also to interfere in a somewhat arbitrary manner with the financial affairs of the asylums. The committee which took the most active part in thus contesting the order of the Board was that of the Richmond Asylum in Dublin. Into the rights and wrongs of their action in this matter, it is not our present intention to enter, as from a medical standpoint they are not of so great importance as are the sequelæ of the primary position assumed by the committee. It is sufficient to say that in the defence of that position the Committee had the complete support of their medical superintendent—Dr. Connolly Norman. The sequelæ are, however, of the most widely reaching importance not alone to the resident superintendents of asylums throughout Ireland and the medical profession generally, but also to that large section of the public who desire that the control of the feeble-minded should be in such hands that advances in the treatment of mental disease may result and not retrogression.

The dispute between the Richmond Asylum Committee and the Local Government Board ended when a mandamus was obtained by the latter body compelling the committee of management to fall in with the terms of the Public Bodies Order. This mandamus was not resisted by the committee, because, according to the committee's version of the matter, the Local Government Board made certain concessions to them. It was alleged that one of these concessions empowered the Committee to delegate to other officers certain duties which had been up to that time in the hands of the medical superintendents. The letter supposed to contain these concessions was not made public at the time by the committee, but subsequently a portion of it found its way into print, and it was then found to state in the clearest manner that "the intention of Parliament was to render the medical superintendent responsible for the entire management of his particular institution, subject, of course, to the superior control of his committee and other duly constituted authority. It rests with the resident medical superintendent, therefore, to permit books and documents to be prepared, verified, and kept by subordinate officers, subject to his supervision and control. He cannot, however, be permitted to divest himself of the responsibility for seeing that they discharge these duties in a satisfactory manner." It thus appears that in the most definite manner the Local Government Board refused to grant the so-called concession empowering the Committee to delegate the duties of the medical superintendent to other officers.

The sequelæ of the events we have thus briefly related may be said to commence from this point, and we shall relate them equally briefly. The Committee of the asylum keeping up still their attitude as a defender of the liberties of elected bodies, and still posing as the victim of the Public Bodies Order, although their attitude on this point was final when they allowed a mandamus to issue by default, have in reality entered on an entirely new crusade, the object of which is to deprive the medical superintendent of his position as the supreme head of the asylum, subject to the control of his committee, and to substitute for him a new authority to be known as the Chief Clerk, whom they have actually described as "their chief executive officer." In pursuance of this policy at the last meeting of the Asylum Committee held on Thursday last, the chairman of the committee proposed the following resolution :—

"The Joint Committee affirm their order holding the Chief Clerk responsible for conducting all correspondence of a non-medical character. All correspondence covered by this minute must in future, if addressed to any other official, be handed to the Chief Clerk."

Moreover, in further pursuance of it, the summonses to attend the meeting for apparently the first time were sent out signed by the chief clerk and not by the medical superintendent.

The speech of the chairman, in which he endeavours to justify his opposition to the present and legal position of the medical superintendent, does not appear to us to be either convincing in its logic or to be justified by the past relations of the medical superintendent to the Committee. The chairman is a most able gentleman, but when he states that he will not be a party to the farce of attempting to hold an official responsible for duties which he is physically unable to perform or even to supervise, we fear that he allows his desire to appeal to the unthinking public to run away with his common sense. May we ask him two questions? Did he ever hear of a head official of any great institution who was capable of physically performing the duties for which he was responsible? The answer is so obvious that we should have concluded that the chairman had been incorrectly reported, had he not previously stated that the Local Government Board had delegated to the medical superintendent the *personal* inspection and rejection of every cast-off garment of the 2,900 inmates of the asylum. Of supervision, however, the responsible head of an institution must be capable, and so follows our second question. How comes it that if Dr. Connolly Norman has been all these years incapable of supervising the institution of which he is the legal head, that not a single instance of neglect can be brought up against him; how is it that at the end of twenty years' service the Committee deliberately state that they are satisfied with his record; and how is it that Mr. Jones, as chairman, has allowed so gross a scandal to continue?

The asking of questions is at times a vain pursuit, but having once commenced them perhaps we may be allowed to ask others. How is it that the chief clerk was allowed to represent himself to the Committee as the lineal descendant of the last secretary of the institution, seeing that some twelve years ago the office of secretary was deliberately abolished with the object of preventing dual control? How does it come about that the Committee were told that, the answer given by Mr. Herbert Gladstone to a question asked by Mr. Gogan in the House of Commons was as follows :—

"The Clerk of the Asylum is entrusted by statute with the keeping of accounts, books, and documents in respect of which he is therefore directly responsible to the Committee. As regards Scotland, clerks and treasurers of District Lunacy Boards are naturally solely responsible to those Boards."

when Mr. Gladstone's actual answer reads thus :—

"There are no secretaries or accountants in public asylums in England and Wales. The officers who deal with the supply and distribution of stores, the keeping of certain books and documents, and of the accounts of receipt and expenditure, are (1) the clerk and steward, the two offices being almost invariably held by the same person; and (2) an outside independent auditor. The former being resident is usually subordinate and immediately responsible to the medical superintendent, who has paramount authority in the asylum subject to the supreme control of the committee of management, statutorily called the visiting committee; the latter is responsible, and reports to the visiting committee alone. The clerk of the asylum is entrusted by statute with the keeping of accounts, books, and documents, in respect of which he is therefore directly responsible to the visiting committee. As regards Scotland, clerks and treasurers of district lunacy boards are naturally solely responsible to those boards."

We have no desire to represent the chairman's views in anything but the most exact manner, but there must be something incorrect in their mode of expression

when they lead the daily press to head its report of the committee's meeting with such notices as "New Local Government Board Ukase"; "Chief Clerk's Duties imposed on Dr. Norman." What is the new ukase, and what duties of the chief clerk have been imposed on Dr. Norman?

We think that if the chairman had been wise he would not have allowed himself to be drawn into an attempt to blind the general public to the true state of affairs. The Local Government Board have issued no new ukase, they have drawn the attention of the committee to the statutory duties of the medical superintendent, and they have intimated that they will not allow those duties to be delegated to a new official. The chief clerk's duties have not been imposed on Dr. Norman, but a deliberate attempt has been made to remove the medical superintendent from his position as supreme head of the institution. This is the vital point in the whole matter, and that which has compelled us to devote so much space to what at first sight may appear to be a trivial dispute between medical superintendent and managing committee. The question at issue is not whether Dr. Norman is to personally examine the cast off clothes of some 3,000 patients, as the chairman would have us believe, but whether the management of lunatic asylums throughout Ireland is to be removed from the medical superintendents and vested in minor officials. Mr. Jones has endeavoured to insert the thin edge of a wedge calculated to shatter the firm foundation on which the treatment of the insane has been gradually placed. Should its insertion be permitted, the time will soon arrive when instead of hospitals for mental disease—the position which lunatic asylums should occupy—we shall witness a reversion to the mad-house of the past. We are confident that the last person who desires such a state of affairs is the very capable chairman of the Richmond Asylum, but we fear that, like many other well intentioned persons, he has not looked forward to the ultimate consequences of his, no doubt, well-intentioned actions.

It is well to know that the serious attack on asylum management has been brought to the notice of the Medico-Psychological Association of Great Britain and Ireland and that the following resolution has been unanimously adopted by that body:—"The Medico-Psychological Association of Great Britain and Ireland, having learnt, through reports in the public press, of a movement in Ireland tending to lessen the authority of the resident medical officers of asylums, desires to express in the strongest manner its conviction that any such change would certainly result in injury to the patients, and would be in direct opposition to all progressive and enlightened treatment of the insane." With prudent foresight, the Association have further directed that a copy of this resolution shall be delivered *into the hands* of the Chief Secretary for Ireland.

LABORATORY NOTES.

ALLENBURYS' FOODS FOR INFANTS.

A SHORT hour in the train, a walk through the somewhat quiet village of Ware, a stroll for half a mile along the banks of the canal (Lea Navigation) where many disciples of Isaac Walton sleepily regard and probably silently anathematise the unaccustomed disturbers of the tow path, a passage over a rustic bridge overlooking a lock, a hundred yards along a road, and Messrs. Allen and Hanbury's factories are reached. The road separates the part devoted to the manufacture of jujubes and soaps, the grinding of drugs, the distilling of oils, &c., from the buildings where the three Allenbury foods are made. Leaving the latter block of buildings on the right as a *bonne bouche*, the investigator may employ with advantage some little time in viewing the various methods of filling the jujubes—making, fashioning into various shapes, stamping and packing soaps, dealing with many different drugs, poisonous and non-poisonous, distilling oils, especially sandalwood oil; but there are two things that must strike the observer during his pilgrimage through the various departments; the first is the scrupulous cleanliness that exists everywhere, not only in the machinery, not only in the floors, walls, etc., of the sheds, but also in the persons and dress of the employees, both male and female; the second is—and how important it is in these days of strikes and unemployed—the absolute happiness, combined with a look of pleasure in their work, which pervades the faces of all the work-people. Crossing the road again and also a bridge over the river Lea itself (the power of the stream being here mechanically utilised) we reach the various buildings in which the Allenbury foods are made. One of the first things to attract attention is the endless stream of milk carts going and coming; this can be quite understood if it be realised that thousands of gallons of milk are delivered daily at the factory. The milk is tested by a trained chemist to ascertain whether it is of the requisite quality. It is most interesting to follow in the different houses the processes through which the milk goes before it is finally reduced to a fine dry powder ready for packing. The most important, as the cow's milk is to be transformed into a food for infants, are the extraction of the excess of casein, and the making good of the deficiences of fat and milk sugar, both these being effected after the cream has been temporarily removed by the milk being passed through separators. The reduction to a powder is brought about by evaporating in vacuo. Here, again, one is struck by the perfect cleanliness of all the buildings, even of the engineering workshop, and with the contented faces of the employees; the cleanliness is not only superficial, but is also hygienic and sanitary. From analysis of these infants' foods, No. 1 for the first three months of a child's life; No. 2 from third to sixth month; No. 3 after six months—we find them absolutely free from harmful bacteria and besides they are so prepared that they approximate as closely as possible to human milk, and as such they are a boon to humanity especially in the present day, when unfortunately fashion on the one hand and hard work by the female breadwinner on the other prevents most women giving their babies the sustenance provided by Nature.

REVIEWS OF BOOKS.

THE TREATMENT OF SPINAL CURVATURE. (a).

THIS book constitutes an instalment towards a complete work engaged in by the author on "The Deformities, Debilities, and Deficiencies of the Spine." Some previous parts, as that on "Caries," already published, deal with singular and particular diseases of the spine only. The present volume reviews the broad principles which underlie the successful mechanical treatment of all lapses of the spinal column. The author, Mr. Heather Bigg, states:—"All errors of the spine, whatever their origin, whether from disease or disorder, are mechanical in results, and all treatment of such errors must also be mechanical in method and intent." The essay is written to substantiate the above statement by evidence which the author considers as indisputable, and by a critical analysis of other methods of treatment.

The treatise is divided into seven sections. Section I. discusses the primary principles of mechanical treatment. Sections II. and III. give an interesting account of the evolution of mechanical treatment from the time of Hippocrates, B.C. 400 to A.D., 1870. About the latter date the author commenced to make a special study of this subject. Section IV. deals with adjunctive treatments used about 1870, as the Couch, the Seat, and the Boot treatment. Section V. is the most important. It describes the apparatus as perfected by the author, and discusses fully the principles of

(a) "An Essay on the General Principles of the Treatment of Spinal Curvatures." By Heather Bigg, F.R.C.S.Ed. London: J. and A. Churchill, 1905. Pp. viii. and 240.

mechanical treatment employed in its construction. In this connection Mr. Bigg has the advantage of being able to use for his guidance the careful record of cases dating from 1825 to 1870, in which the mechanical treatment was carried out by apparatus made by his grand father, Mr. Henry Bigg, and his father, Mr Heather Bigg. The principles involved are two—(1) The weight of the trunk must be up-buoyed; (2) active force of some kind must be brought to bear on the errant parts of the body. At the same time, vacant spaces must be left over the recessions of bodily error, so that these parts may have ample room left into which they may pass as the body straightens. The whole method of treatment depends on the graded alterations in the shape of the appliance, so that as the body changes for the better the spring force of the appliance may follow it up by persistent steps until successively enforced improvements culminate in complete straightness. The objection to Sayre's jacket is that though it presses on the prominences, it also presses with equal force on the recessions, which are therefore precluded by lack of room from any rectification. An efficient and easy method of overcoming this difficulty when using plaster of Paris jackets in hospital practice is described. Section VI. contains a criticism on other methods of treatment in use from 1870 to 1905. Sayre's jacket and the gymnastic treatment are particularly dealt with. Section VII. consists of a critical analysis of Mr. Roth's book on the gymnastic treatment of spinal curvature.

The essay on spinal curvatures is well printed, and suitably illustrated with the author's own photographs and sketches. In it Mr. Bigg constitutes himself the champion of the mechanical treatment of spinal curvatures, and as such attacks other methods vigorously and at considerable length. But in so doing he does not fail to make clear his own position, and also to produce a work which will be found both interesting and instructive. S.

BELL'S SURGERY FOR NURSES (*a*).

THE sixth edition of this ever-popular book needs no detailed notice. The former edition has been revised and brought up to date, and forms a model of clear and concise popular scientific writing. In addition to the technical matter an appendix appears for the first time "on the relation of the trained nurse to the profession and the public." This survey is written with keen insight into the facts of a somewhat complicated relationship, and should be carefully perused by every member of the nursing profession. The book is full of apt aphorisms, as for example, "nurses are employed rather by the medical profession than by the public." We can cordially recommend this little volume to all interested in the subject.

YEAR-BOOK OF PHARMACY. (*b*)

THIS year-book contains a wealth of information for the pharmaceutical chemist, and much also that is of interest to the ordinary medical practitioner. We have here abstracts of the papers dealing with Pharmacy, Materia Medica and Chemistry, which have been contributed to British and Foreign Journals from July 1904, to the end of June, 1905. It is impossible with the space at our disposal even to mention the many papers and reports which the volume contains, and to the book itself we must refer our readers who wish to find out what has been done in the various departments of pharmaceutical chemistry and where it has been reported. We should wish especially to draw attention to Dr. W. E. Dixon's plea for the Bio-chemical standardisation of certain drugs, which cannot be satisfactorily assayed by chemical means. Such drugs are the members of the digitalis group, ergot and Indian hemp. The latter a drug of considerable importance is perhaps the most variable of all the materia medica, yet the ordinary method of assaying it by the determination of the total amount of resin which it contains is said to be practically worthless. If such potent drugs are to be used in the treatment of disease, at least the physician should demand that preparations of them should be of uniform strength. This being so, we hope that in the near future the bio-chemical method of standardisation, where necessary, will become compulsory.

(*b*) "Year-Book of Pharmacy with the Transactions of the Pharmaceutical Conference at the forty-second annual meeting, held in Brighton, July, 1905." Editor of the Year-book, J. C. Braithwaite. Editors of Transactions, E. Saville Peck, M.A., and Edmund White, B.Sc., F.I.C. London: J. & A. Churchill, 1905.

WALLER AND SYMES ON PRACTICAL PHYSIOLOGY (*a*).

THE second part of this useful laboratory hand-book deals with those exercises in chemical and physical physiology which students can perform for themselves, together with more advanced operations partaking of the nature of formal demonstrations. Nearly half the book is taken up with the experiments connected with the blood and circulation. An ingenious sphygmomanometer (human) is described in which the radial artery is compressed by an inflated finger-stall joined up to a small mercurial manometer. The remainder of the book is occupied with food-stuffs, digestion, muscle and urine. The directions given throughout are concise but quite explicit, and there are some useful diagrams and charts.

LITERARY NOTES.

THE question is sometimes asked, "Who reads all the medical books that are published?" an impossible question, of course, to answer. Nor is the solution assisted by a glance through Mr. Lewis's new "Catalogue of Medical and Scientific Library," just issued. This only includes works from the various medical publishers during 1902–1905, yet it contains upwards of 1800 titles, and catalogues compiled by Mr. Lewis prior to this date give 7,200 titles in addition. When it is remembered that for the subscription of a guinea per annum to this circulating library access can be had to this marvellous production of medical authors some faint idea of labour if not of study can be gleaned.

MR. WILLIAM FIELD, M.P., sends us a copy of his pamphlet entitled "Ireland and Imperial Expenditure." It contains reprints of four articles contributed to the *New Ireland Review*, together with newspaper comments, questions in Parliament, letters, and other documents, relative to the subject. Mr. Field's writing is in his usual trenchant style, and he gives many striking examples in support of his contention that a fair proportion of Imperial expenditure does not go to Ireland. Among other illustrations are the facts that Army Medical Service advertisements are refused to any medical papers outside London and that successful candidates for the Royal Army Medical Corps are, or were, bound to purchase their uniforms from London tailors.

MESSRS. DOLLARD, LTD., of Dublin, publish a very excellent little book by Surgeon-Lieutenant MacCabe, entitled "War with Disease." It consists of four lectures on the subject of preventive medicine, delivered a few months ago to the Officers, N.C.O.'s, and selected men of the Cavalry Brigade at the Curragh, by request of General Rimington. Dr. MacCabe has performed a very difficult task with complete success. He has explained in straightforward, plain language, the essentials of personal hygiene as applicable to soldiers, and this not only in general, but in relation to certain of the more important diseases. The lectures are avowedly popular, but they are at the same time thoroughly scientific. They should be read by every soldier, whether commissioned or private.

MEDICAL NEWS IN BRIEF.

St. Mary's Hospital, London.

AT the annual distribution of prizes to the students of the medical school last week the Dean (Dr. H. A. Caley) reported that the number of students was approximately 230. The examination results for the year had been satisfactory, 25 students had obtained diplomas of M.R.C.S. and L.R.C.P., 18 the M.B. degree of the Universities of Oxford, Cambridge, London, or Durham, and four that of M.D. Mr. M. F. Kelly had been awarded the gold medal in surgery at the B.S. examination of the University of London, and Mr. A. F. Hayden, who obtained the third place in the entrance examination for the Indian medical service, had won the Montefiore bronze medal and prize in military surgery and the Martin prize in military medicine. In referring to the naval and military medical services, the Dean mentioned that St. Mary's was represented by 148 former students —64 in the R.A.M.C., 48 in the Indian medical service, and 36 in the medical service of the Royal Navy. Surgeon-General Sir Alfred Keogh, Director-General of the Army Medical Service, gave away the prizes, and, addressing the students, said he was glad to see that the school was so well represented in the public services, especially in that branch to which he had the honour to belong. The steps taken by the General Medical Council would uphold the honour and dignity of the profession, and their outlook was better than it had ever been before. The company afterwards proceeded to the entrance hall of the Clarence wing, where Mr. Harben, as chairman of the board of management, invited Sir Alfred Keogh to unveil a bronze mural tablet in memory of seven members of the hospital and medical school who fell in the South African war. In doing so, the Director-General said that he hoped the memorial would be an incentive, if the country ever required their help, to the students to come forward and do as their brave comrades had done.

Royal University of Ireland.

THE RIGHT HON. SIR ANDREW M. PORTER, BART., Master of the Rolls, and Sir William Anson, Bart., D.C.L., M.P. for Oxford University, held a public visitation at the Royal University on Friday last, for the purpose of inquiring into the existing regulations respecting the holding by students of the University of fellowships, scholarships, or other emoluments or prizes in other Universities or colleges than the Royal University.

Mr. C. F. Doyle, K.C., Examiner in Law to the University, said that the question with which the visitation was concerned arose on the construction of Section 9 Sub-section 14 of the University (Ireland) Act of 1879, which was as follows:—

Provision shall be made that no student holding any exhibition, scholarship, fellowship, or other similar prize in any other University or in any college attached to a University, or in any college endowed with public money, shall hold any of the said exhibitions, scholarships, fellowships, or other prizes in the University without taking the value of such previous exhibition, scholarship, fellowship, or other similar prize into account.

The doubts and difficulties which had arisen were almost entirely confined to the question as to the interpretation to be put on the words "holding" and "hold" in that sub-section. In accordance with that enactment the University regulations contained the following provisions.:—

No student holding any exhibition, scholarship, fellowship, or other similar prize in any other University or in any college attached to a University, or in any college endowed with public money can hold any of the exhibitions, scholarships, fellowships, or other prizes in the Royal University without taking into account the value of such other exhibition, scholarship, fellowship, or other similar prize.

Sir William Anson said the visitors had come to the conclusion that the resolution of the Senate proceeded on the assumption that it was possible to construe the word "holding" as "having held." The visitors did not consider that that was a possible construction, that the student who was disqualified from holding a prize of any sort at the Royal University must be actually holding some prize of the sort included under the Sub-Section. It would follow, therefore, that the resolution of the Senate was *ultra vires*. They (the visitors) considered that the word "previous" could not be construed, as suggested, as equivalent to "aforesaid." Therefore, it was possible for a student to hold two of these prizes at the same time, so long as at the moment he was awarded a prize at the Royal University he was not holding a similar prize previously obtained. They further held that a scholarship which had run out in June at the end of the academical year would not affect an exhibition or other prize obtained at the Royal University and awarded in July. In regard to a sizarship in Trinity College, they were of opinion that it must be regarded as a "previous exhibition, scholarship, fellowship, or other similar prize," and, therefore, as not tenable by the students of the Royal University. As regarded the appeals from students who held allowances from the Department of Agriculture, the views of the visitors were that these are not held from colleges endowed by public money, but from a public department, and that therefore they are not affected by the words of the sub-section.

Army Contractor's Potted Ham.

ON the 19th inst., the Brentford Bench had before them three summonses arising out of the sale of potted meat. The defendants were Messrs. Dickeson and Co., Limited, London, and Mr. A. J. Mileson, of Brentford. There were two summonses. In the first Messrs. Dickeson were charged with having sold potted ham containing 0·74 per cent. of boracic acid, equal to 80 grains of borax per pound, and, further, that the sample had been coloured with oxide of iron. In another instance, it was alleged to contain 1·2 per cent., equal to 129 grains per pound. Against Mr. Mileson the summons was for selling brawn which contained 0·398 per cent. of boracic acid, equal to 42.9 grains of borax per pound. Also that the sample was coloured with a pink coal tar dye. The summons against Messrs. Dickeson alleging 1·2 per cent. of boracic acid was adjourned on a question of analysis. The case as regarded the sample containing ·74 of boracic acid was then dealt with. Mr. Smith said the defendants had large contracts for the Army. The potted ham was purchased in the canteen at Hounslow Barracks, three tins for a penny apiece. Mr. Beavan, analyst, said that if good meat was used, and it was properly sterilised and kept in hermetically sealed tins, the product would keep without the application of boracic acid. Dr. J. S. Sykes, Medical Officer of Health, gave evidence that the use of boracic acid was injurious to health. Dr. W. H. Wilcox, Lecturer on Public Health at St. Mary's Hospital, held that boracic acid ought not to be used in potted food at all. Two children were admitted to the hospital suffering from malnutrition. They were fed on cream which it was subsequently ascertained contained boracic acid.

They died, and it was the opinion of himself and other physicians that the use of this acid had brought about the deaths. Mr. Otto Hehner, for the defence, said he had examined samples of all the best makes of potted meat. Out of 23 samples, 20 contained boracic acid. Experiments had been made daily on forty millions of people in England for fifteen years, and no conclusive case of injury had been proved. Professor S. W. Tunnicliffe said he was a member of the Departmental Committee appointed by the Local Government Board to inquire into the use of preservatives and colouring matter. As a result of his investigation and the evidence before the Council, he formed the opinion that the use of boracic acid was justifiable, and was unlikely to be injurious to a healthy ordinary individual. The Chairman said they were unanimously of opinion that the article sold was rendered injurious to health by the addition of as many as 52 grains per pound of boracic acid to it. The defendants were fined £5 and fifty guineas costs. The case against Mr. Mileson was taken next. The Bench fined defendant 40s. and costs.

[Elsewhere, in the present issue, we comment upon a conviction for boracic acid adulteration, with certain recent medical views upon the whole matter.—ED.]

Irish Medical Schools' and Graduates' Association.

A CONVERSAZIONE and dance will be given by the Irish Medical Schools' and Graduates' Association, at the Hotel Great Central, London, on Thursday (to-morrow), July 26th, at 9 p.m., to meet the Council and Representatives of the British Medical Association. Members of the Irish Medical Schools' and Graduates' Association can obtain tickets from Mr. Canny Ryall, F.R.C.S.I., 85, Harley Street, W.

The Coal Tar Jubilee.

TO-MORROW Dr. Perkin, whose name is associated with the discovery of sulphonal, aspirin, carbolic acid, and anti-pyrine, and the analine dyes will be presented at the Royal Institution with his portrait and bust on the occasion of the Jubilee of the Coal Tar Industry. In the evening a banquet will be held at the Whitehall Rooms, at which many distinguished guests are expected.

British Pharmaceutical Conference.

THE annual session of the Pharmaceutical Conference is taking place at Birmingham this week, under the presidency of W. A. Naylor, F.I.C., F.C.S. The daily meetings will be held in the University, the last being on Friday next. Receptions will be held by the Lord Mayor and by Mr. Thomas Barclay, J.P. (vice-President), to the medical profession, about forty of whom have accepted invitations, and to members of the Conference. Mr. Barclay's reception will be held this evening (Wednesday) in the Botanical Gardens, which will be illuminated, a display of fireworks will take place after which a cinderella dance. Visits will be paid during the session to Messrs. Cadbury's model village, to the Royal Porcelain works at Worcester, Messrs. Osler's glass works, to Kenilworth, and other places of interest, and altogether the meeting promises to be of exceptional interest.

Food Inspection.

IN a report just issued, the Medical Officer of the Borough of Holborn recommends that the name and address of the manufacturer. and the date of canning of foods should be impressed on the cans; that tins which were known in the trade as "doubtfuls" should be deemed unfit for home consumption; that food intended for canning should be inspected by independent officials prior to being canned; that all foods should be canned under strictly hygienic conditions; and that the use of preservatives in canned foods should, under no circumstances be permitted. The Public Health Committee reports that during the past month 32 samples of canned or potted meats of various kinds were purchased and submitted to the borough analyst for examination, from whose report it appears that, with the exception of one tin, which was "blown," and which was returned, the whole of the meat was found to be generally in good condition. Preservatives were detected in only four cases, and in very small quantities—viz., boric acid to the extent of 0.5, 0.125, 0.07, and 0.05 respectively; in a few instances slight traces of nitrates were discovered, probably added for colouring purposes. "It is of interest to note," add the committee, "that the preservatives were discovered in home-canned goods, none being found in American or other imported tins."

Royal College of Surgeons of Edinburgh.—The Fellowship.

THE following gentlemen, having passed the requisite examinations, were at a meeting of the college held on 20th inst., admitted ordinary Fellows—Charles Henry Allen, M.B., Ch.B., Metheringham; James Reginald Atkinson, M.B., C.M., Crewe; Kaikhusru Dadabhoy, L.R.C.S.E., Edinburgh; John May Darling, M.B., Ch.B., Edinburgh; William Henry Duncan, L.R.C.S.E., Maryhill; Samuel Linley Heald, M.B., Ch.B., Leeds; Thomas Walter Irvine, M.B., C.M., Major, Indian Medical Service; Joseph Alan Longley, M.B., Ch.B., Leeds; John Clark Muir, M.B., Ch.B., Edinburgh; John King Osborne, M.B., C.M., New South Wales; George Potts, L.R.C.S.E., Maidstone; Andrew Taylor Ross, M.D., Glasgow; David Herman Wessels, M.B., Ch.B., South Africa, and Alfred Lambre White, L.R.C.S.E., Edinburgh.

Royal College of Physicians and Surgeons.

SECOND PROFESSIONAL EXAMINATION.—Candidates have passed this examination as undernoted: July, 1906—R. Adams, Miss I. M. Clarke, E. C. Deane, H. S. Meade, J. Menton, Miss A. F. Nash, and Miss C. F. Williamson (with honours), P. N. Allman, S. J. Barry, G. E. Beggs, B. G. S. Belas, W. Breen, H. F. Blood, T. G. Brown, P. A. Doyle, E. Dundon, B. H. Farrell, J. F. Gibbons, Miss M. K. Griffin, E. Harrison, F. N. Harvey, W. Hederman, H. S. Johnston, C. Kelsall, P. M. J. Power, R. Power, R. H. Taaffee, P. T. Warren, J. D. Williams, Miss Nora Williams, and O. W. J. Wynne.

THIRD PROFESSIONAL EXAMINATION.—S. Blake, T. C. Boyd, W. H. Bomford, S. Broderick, T. Cormac, W. F. S. Davis, J. Ellenbogen, B. Foley, W. F. Lane, G. S. Levis, J. E. Moffatt, J. M'Namara, C. M'Queen, J. V. O'Hagan, W. H. O'Riordan, D. O'Sullivan, G. F. Shepherd, and J. M. Warnock.

Trinity College, Dublin.

Intermediate Medical Examination—Part II.—Richard P. Hadden, Samuel F. A. Charles, and John L. Phibbs (passed on High Marks); Henry H. Ormsby, Albert V. J. Richardson, Herbert V. Stanley, Frederick A. Anderson, Charles W. Laird, George Halpin, George B. McHutcheson, Gerald G. Mecredy, Robert de C. Wheeler, William E. M. Armstrong, Edward J. H. Garstin, Frederick R. Sayers, Duncan F. Hunter and Henry R. Kenny, equal Arthur H. Laird, Harold S. Sugars, Richard T. Attridge, John C. Baker, William H. Sutcliffe, William H. M'Carthy, Frank Smartt.

Fitzpatrick Scholarship:—Ralph S. Oldham.

Medical Scholarships:—Anatomy and Institutes of Medicine—Johannes C. Pretorius, Trinity College Scholarship; Samuel F. A. Charles, Stwart Scholarship. Physics, Chemistry, Botany, and Zoology—Arnold K. Henry, Trinity College Scholarship; David Duff, Stewart Scholarship. Purser Medal in Institutes of Medicine—Richard L. Hadden.

Society of Apothecaries of London.

THE following candidates having passed the usual examination, have received the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—H. J. May. J. L. Meynell, E. Morris, and E. J. F. Thomas.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS.

ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

The Surgical Aspect of Anuria.—Cumston (*Glasgow Medical Journal*, July, 1906) outlines a classification of conditions giving rise to various forms of anuria. Those cases resulting from reflex action are first considered. To this class belong the anuria of hysteria, toxic anuria arising from the intestinal canal, and also instances of suppression of urine caused by an irritation arising in one kidney, which irritation, by what is probably a reflex action, prevents the secretion of urine from the healthy organ as well. The anuria in these cases can usually be traced to a reflex contraction of the renal bloodvessels, especially the arteries. A cure followed deep chloroform narcosis in a case of absolute anuria which had lasted eleven days. Obstruction of one ureter as from calculus, or in movable kidney sometimes gives rise to the so-called sympathetic anuria. Cohnheim came to the conclusion, after some experimental work, that in complete obstruction of the ureter hydronephrosis can only occur to a mild degree, because the enormous tension set up rapidly produces a failure in the secretory power of the organs; and that marked hydronephrosis arises only in incomplete obstruction of the ureter. Anuria may follow the removal of one kidney. It arises under these conditions either from the fact that the opposite kidney is diseased and functionless or that the heart, which may have been undergoing pathological changes for some time, has its action weakened from the narcosis and loss of blood, so that ischæmia of the kidney results, causing rapid degeneration of the renal epithelium, and with this cessation of its function. The author considers that aseptic technique in nephrectomy is of more importance than the choice of the anæsthetic. He points out the deleterious action on the kidney of certain antiseptics, as carbolic acid, iodoform, and especially bichloride of mercury. In anuria due to cholera a marked venous hyperæmia of the kidney is found. The oliguria and anuria in severe cases of diffuse nephritis appears to find an explanation through the almost complete blocking up of the urinary canals with casts. Renal calculus is the most frequent cause of anuria. There is only one recorded case in which both ureters were obstructed by calculi at the same time, thus causing anuria, the two kidneys at the same time being in perfect functional order. There is the possibility for the occurence of calculus anuria, apart from reflex anuria, when only one kidney exists. Schwenger reports a case of this kind, where autopsy revealed the complete absence of the left kidney. Anuria due to ureteral obstruction from blood clot or compression from without is rare, and probably only occurs when the other kidney is functionally destroyed. In case of anuria operation should not be delayed longer than forty-eight hours. The kidney should be opened in order to give exit to the urine. The author cites a case of anuria of puerperal origin, in which bilateral decapsulation was done. Although some improvement followed, the patient died four days after the operation. The author believes that nephrotomy might possibly have saved the patient's life. S.

Some Points on the Surgery of the Lung.—Sir William Macewen (*Brit. Med. Journ.*, July 7th, 1906) discusses the condition of collapse or otherwise of the lung in perforating wounds of the chest. A man fell across a circular saw while in motion. As a result of the accident a slice was taken off the outer aspect of the right side of the chest and the visceral pleura was left exposed over an area as large as the palm of the hand. This exposed portion of the lung lay in contact with the atmospheric air and there was no collapse. In order to secure a bleeding intercostal artery, the visceral and parietal layers of pleura were separated, thus admitting air into the pleural sac. The lung as a result receded from the chest wall. On bringing the visceral and parietal layers of pleura together by direct pressure on the chest wall the two pleural layers coalesced and the lung again filled the aperture, as it did prior to the admission of air into the pleural sac. On the patient suddenly tossing round on to the uninjured side, the air again entered the pleural sac, and the lung receded markedly from the thoracic wall. When turned gently on his back pressure being made at the same time on his thorax, the two pleural layers were again brought into contact. The wound was at once closed with the flap, pressure being meanwhile applied, and the external parts were suitably fixed to prevent undue expansion of the chest on that side. From the observations of this and similar cases, the author concludes that should collapse of the lung occur to a limited extent that organ can be expanded again by the simple expedient of bringing together the two layers of the pleura and securing intimate contact between them. The normal amount of lubricating fluid between the two layers of the healthy pleura, usually augmented by the thin layer of liquid blood, aids in the coalescence of the two serous surfaces. Capillary attraction exists between the two moistened surfaces. The action of a biconcave meniscus is distinctly visible during the coalescence and separation of the two serous layers. In a case of traumatic pneumothorax it was seen that the lung was torn and a portion of the visceral pleura invaginated into it. A portion of the rib over the wound in the lung was removed and the visceral pleura stitched across the gap in the lung, which soon filled with blood clot; a light pad of antiseptic gauze loosely applied was inserted between the lips of the thoracic wound, which was thus kept open, and any air which might come from the lung would thus escape externally. Firm pressure was kept on the external thoracic wall above and below the wound by means of adhesive plaster, as if for broken ribs, and a firm roller bandage was applied. The relief to the patient was immediate and lasting. The wound in the lung soon closed, and the tissues of the thoracic wall were then brought together. In pathological conditions, when the pleural surfaces are covered by plastic exudation or layers of fibrinous patches, the power of molecular cohesion between the surfaces is greatly lessened or lost. There is also less elasticity and less recoil in the pulmonary tissue, and therefore less tendency to collapse and less capacity of expansion. Hence the necessity in many such cases of removing a sufficient portion of the osseous walls to permit the thoracic wall to come in contact with the lung. In the author's opinion the causation of primary shock in admission of air into the pleural sac is really due to the effect upon the heart. The vessels of the pulmonary circulation only anastomose at the periphery of the lung. The result of contraction of the lung, which takes place mostly at the periphery, is that the flow of blood through the minute vessels is greatly impeded or even arrested. The sudden arrest of flow of blood into the lung from the right ventricle produces a staggering effect on the heart which falters in action and results in dyspnœa and lividity of the cutaneous surface. S.

Paralysis of Recurrent Laryngeal Nerve in Mitral Stenosis.—Frieschner (*Wiener Med. Woch.*, 1905, No. 52) reports a case of a woman, æt. 30, who was suffering from mitral stenosis and regurgitation, and who developed paralysis of her left vocal cord three weeks before her death. At the autopsy the cause was

proved to be compression exercised by the greatly dilated and hypertrophied left auricle. This pressure was not, however, direct, but was exercised through the pulmonary veins and pulmonary artery, which by being displaced forwards compressed the recurrent laryngeal nerve against the aortic arch. The nerve fibres were degenerated upwards from this place. Up to this three possibilities have been regarded as the cause of the association of recurrent paralysis and mitral stenosis, namely (1) direct compression by the left auricle; (2) indirect pressure by the left auricle through the pulmonary artery; (3) similar indirect pressure exerted through the medium of the ligamentum arteriosum. M.

Primary Tuberculosis of the Conjunctiva.—Dr. J. J. Thompson (*Annals of Ophthalmology*, January, 1906) reports a case of the above in which the appearances were atypical rendering a diagnosis between tuberculosis and syphilis difficult. The patient sought advice about a pre-auricular gland which had become enlarged. The corresponding eye had felt "peculiar" for four weeks. The upper lid was very slightly swollen, and on the conjunctival surface there was a small (2 mm.) ulcer, with clean-cut edges, clean base (unusual), and no surrounding induration. Notwithstanding the absence of the induration, Thompson had a strong leaning towards the ulcer being syphilitic. There was no family history or physical signs of tuberculosis. The excised gland gave anatomical tubercles with a fair number of giant cells. A guinea-pig whose peritoneum had been inoculated with scrapings of the ulcer, died in 35 days from general tuberculosis. The ulcer and surrounding tissues were thoroughly removed. Progress was favourable, the ulcer being healed in two weeks, and the patient kept in the best of health. Thompson thinks the infection must have occurred through a small abrasion of the conjunctiva, as, according to Valude, the tubercle bacilli will not penetrate the intact conjunctiva. M.

Interscapulo-thoracic Amputation for Sarcoma of the Scapula.—John Douglas (*New York Med. Journ.*, June 9th) records a successful case of removal of the arm and scapula for sarcoma. Berger's method was followed: (1) Incision over the clavicle; (2) subperiosteal resection of its outer two-thirds; (3) ligation of the subclavian artery and vein; (4) division of the pectoralis major and minor; (5) injection of the brachial plexus with 1 per cent. cocaine solution; (6) shaping flaps, division of the brachial plexus, division of the latissimus dorsi, with turning back of the arm and scapula; (7) division of the muscles attached to the scapula; (8) closure of the wound. The patient was allowed out of bed on the sixth day. The mortality of the last 153 similar cases is only 7·8 per cent. The average duration of life after the operation is only three years. G.

Renal Casts and their Clinical Significance.—In a paper on this subject, Benjamin Clive (*The Post Graduate*, June) refers first to the origin of renal casts. He believes that they are composed of exuded coagulable elements of the blood, which enter the renal tubuli as a result of pathological changes in the latter, and these solidify, forming moulds (casts) of the tubules. A second theory is that they consist of a secretion from the irritated epithelial lining of the renal tubuli, which later solidifies and forms casts. Lastly the theory is held by some observers that the casts are products of disintegrated renal tubular epithelium, which coagulate and are washed out with the urine. The clinical significance of the presence of the various forms of renal casts is then dealt with. Hyaline casts are not pathognomonic of any one abnormal state; they are common in the urine of most persons over 40 years of age, with, as well as without, the slightest passive hyperæmia of the kidney, or an acute or chronic trace of albumin, and may occur in the urine for years without any evidence of a kidney lesion. This applies also to granular casts the finely granular casts occurring in healthy urines. The coarsely granular usually are associated with marked degenerative changes in the renal epithelium. Epithelial casts point to active or parenchymatous nephritis. Pure pus casts are comparatively rare, and when found indicate an infective suppurative process in the kidney. Blood casts are found in the urine in conditions where hæmaturia is of renal origin, and renal hæmorrhage from any cause may accompany them. They are not in themselves positive evidence of organic renal disease. Fatty casts usually indicate chronic interstitial, or chronic parenchymatous nephritis. Mixed casts are not pathognomonic of any one type of renal disease, their diagnostic value is dependent on their number, and the predominant cellular elements. Waxy casts may occur in the absence of any amyloid disease in the kidney; on the other hand, kidneys which are extensively amyloid may not cause any waxy casts in the urine, their diagnostic value is therefore not high. Cylindroids are found under much the same conditions as hyaline casts, and are of no great significance. Mucous threads may originate from any part of the urinary tract, but are usually found in connection with irritation or inflammation of the lower urinary passages. G.

Analyses of 186 Operations upon the Liver and Gall Passages and the After-Results.—C. McWilliams (*New York Med. Journ.*, June 2) gives a critical analysis of 186 operations on the biliary passages. In 69 of the cases it was possible to follow up the after-history as well as the immediate result of the operation; 65 per cent. were cured; 10 per cent. were improved; 12 per cent. required secondary operations; 9 per cent. developed subsequent hernia in the wound. In 10 per cent. calculi had been overlooked at the first operation. The author then describes fully the cases in which secondary operations had to be performed. From these patients he draws the following conclusions: (1) More thorough search for calculi at the primary operation, splitting the ducts wide open, if necessary. (2) Provided it were possible of performance, a primary cholecystectomy would have avoided the necessity for a secondary operation, in nearly all the cases. (3) In only one of the cases had a primary cholecystectomy been performed. This speaks very strongly for the removal of the gall-bladder at the primary operation, since it seems to give the greatest guarantee against future difficulties, hence the greater certainty of a cure. G.

Injuries to the Eye during Birth.—S. Stephenson (*Brit. Journ. of Children's Diseases*, 1905) related how Beaumont, Snell, Thomson, and Buchanan have reported cases of *dislocation of the eye* during birth. As a depression of the cranial bones has generally coexisted, Thomson and Buchanan designated the injury as an "extrusion," rather than a "dislocation." Stephenson refers to the case quoted by de Wecker, where an accoucheur, mistaking a face for a buttock presentation, managed to gouge out the baby's eye with his finger. Besides injury to the facial nerve, other *cranial nerves, e.g.*, the third, fourth and sixth, may be paralysed from injury during birth. The mechanism of the injury is not known beyond doubt, but it is probably due to fractures of the bones of the orbit or to intra-cranial or intra-orbital extravasation of blood. The transient nature of these paralyses is in favour of the last-named causes. In Küstner's case the third, fourth, sixth, and seventh pairs were affected, the paralysis was found after death to have been caused by hæmorrhages at the base of the brain, and lesions of the orbital walls. M.

The Relief of Cicatricial Orbit.—Dr. J. M. Ball (*Annals of Ophthalmology*, October, 1905) reports two cases of cicatricial contraction of the orbit in which the patients were unable to retain the artificial eye. He performed Maxwell's (Dublin) operation on the lower cul-de sac. On the upper cul-de-sac he made a Thiersch graft. Both cases did well, and after a year the wearing of the artificial eye remained comfortable. M.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

PANCREAS.—There are considerable difficulties about the amalgamation. It was suggested by the Departmental Committee, but a Royal Commission would probably be needed. The Board of Education are now preparing a scheme.

NEMO (Wales).—The matter being hung up leaves us in the dark at the moment. A lecturer in lunacy would be needed at a fully-equipped university.

LECITHIN.—The situation fortunately does not often occur. Your best plan would be to call on the doctor whose name has been mentioned, and tell him the circumstances frankly. We feel sure there is a misunderstanding, and the course we suggest is the right way to clear it up. It would be better not to visit the patient again, if you can avoid doing so, till you have seen the doctor.

HEART FAILURE.

The old cause of death
Was the "shortness of breath,"
But that is too vulgar by far;
The more modern "tale,"
Our hearts must all fail
Before we go "Crossing the Bar."

This foregone conclusion
Is oft a delusion,
But yet when we hear someone dies,
There is never a pause
To consider the cause—
"Heart failure," of course! someone cries. —A. D.

T. W. B.—We think that you have been misled by the information given you. If you refer to any standard work on therapeutics you will find that the treatment suggested is not generally approved by those who have had most experience of it.

SPECIALIST.—The new Code for 1906-7 was issued by the Education Department on July 1st. In it you will find that the changes you anticipate have been included.

APPLICANT.—The post of Assistant Medical Officer of Health for the Orange River Colony has been added to list of pensionable offices, but the appointment has recently been filled.

A FAMOUS NASSAU SPA.

IT so happens that one of our staff is in a position to answer your query about Schlanzenbad. The atmosphere is bracing and the scenery magnificent. From a medical point of view the chief attraction lies in the springs, which are famous for their beneficial action upon many diseases of the skin. The hotel accommodation is excellent. Any further information can be got by writing to Herr Winter, Hotel Victoria, Schlanzenbad, Germany.

ERRATA.—In our review last week of Dr. Shaw-Mackenzie's book on "The Treatment of Cancer," two printer's errors crept in: Glycogen should have been spelled Glycosen, and Crepsin should be read as Erepsin.

ELOMENSIS.—It is not uncommon for dogs to be supplied with artificial limbs after amputation. The whole subject is dealt with in a most interesting way by Professor Hobday in a book recently published by Baillière and Cox on "Diseases of Cats and Dogs."

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 25th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. C. Ryall: Clinique. (Surgical).

THURSDAY, JULY 26th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical).

Vacancies.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. Applications to the Director, School of Medicine, Cairo, Egypt.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £75 per annum, with apartments and rations. Applications to S. J. Leonard, Clerk.

Hospital for Sick Children, Newcastle-on-Tyne.—Male Resident Medical Officer. Salary £100 per annum, with board, lodging, and laundry. Applications to Alf. E. Birch, Secretary, Secretary's Office, Hospital for Sick Children, City Road, Newcastle-on-Tyne.

Lincoln Lunatic Hospital.—Assistant Medical Officer. Salary £100 per annum, with board, &c.—Applications to the Medical Superintendent, The Lawn, Lincoln.

North Cambridgeshire Hospital, Wisbech.—Male Resident Medical Officer. Salary £125 per annum, with furnished rooms, attendance, coals, gas, and washing. Applications to William F. Bray, Secretary, Wisbech.

Preston Royal Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and washing, &c. Applications to Walter Davies, Secretary, 5 Winckley Street, Preston.

Royal Infirmary, Bradford.—Salary £100 per annum, with board and residence in the Infirmary. Applications to Edmund Forster, Secretary.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, and the other usual allowances. Applications to Albert Edward Booker, Clerk to the Guardians, Union Offices, Westbar, Sheffield.

The Cambridgeshire, &c., Asylum.—Second Assistant Medical Officer. Salary £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, 18 Emmanuel Street, Cambridge.

University of Manchester.—Junior Demonstrator in Physiology.—Salary £100 per annum. Applications to the Registrar.

West Bromwich District Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Honorary Secretary, T. Foley Bache, Esq., Churchill House, West Bromwich.

Appointments.

BIRCH, CHARLES, M.R.C.S., L.R.C.P.Lond., Medical Officer to Clayesmore School, Pangbourne, Berks.

CURTIS, WILFRED, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer for the Sixth District by the Liskeard (Cornwall) Board of Guardians.

DOUGLAS, CARSTAIRS C., M.D.Edin., Extra Examiner in Medical Jurisprudence and Public Health in the University of Aberdeen.

GAINER, J. W., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Thrapston District of the county of Northampton.

GOYDER, F. W., M.B., B.C Cantab., Honorary Assistant Surgeon to the Royal Infirmary, Bradford.

HODGE, R. F. VERE, M.B., B.C.Cantab., Resident Medical Officer for the Out-patient Department of Queen Charlotte's Lying-in Hospital.

HUSTLER, G. H., M.B., Ch.B.Leeds, Assistant House Surgeon at the Royal Devon and Exeter Hospital, Exeter.

IRVING, HAMILTON, M.B., B.S.Lond., M.B., Ch.B.Manch., House Surgeon at the Evelina Hospital for Sick Children.

KILVERT, JOHN ELLIS, L.R.C.P.Lond., M.R.C.S., Honorary Surgeon to the Derbyshire Royal Infirmary.

KIRKNESS, W. RONALD, M.R.C.S.Eng., L.R.C.P.Lond., House Surgeon and Assistant Secretary to the West Herts Infirmary, Hemel Hempstead.

MACLAGAN, P. A., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Ayton District of the county of Berwick.

MARSHALL, H. F., M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at the Evelina Hospital for Sick Children.

MORTON, A. STANFORD, M.B., M.S.Edin., Ophthalmic Surgeon to the Italian Hospital, Queen Square, W.C.

Births.

LEWIS.—On July 21st, at Nantile, Bickley, Kent, the wife of C. E. M. Lewis, M.D.Cantab., of a son.

Marriages.

HARRIS—MAYNE.—On July 21st, at St. Peter's, Cranley Gardens, London, Wilfred Harris, M.D., of 61, Wimpole Street, London, to Miss Mabel Mayne, daughter of the late Rear-Admiral Mayne, and niece of Sir Alfred Dent.

MACKENZIE—MORGAN.—On July 18th, at St. James's, West Ealing, Dudley Macdonald Mackenzie, M.D., to Constance, youngest daughter of Captain Morgan, "Belmont," Creigian.

TIBBITS—HARGREAVES.—On July 19th, at St. Mary's, Dover, Edward, eldest son of the late Edward Thomas Tibbits, M.D., of Bradford, Yorks, to Myra Lilian, eldest daughter of William Henry Hargreaves, J.P., of Christchurch, N.Z.

Deaths.

BRAYE.—On July 20th, at Hurstmonceux, King Edward Road, South Hackney, Hardwick Hubert Braye, M.R.C.S., L.S.A., aged 61.

NOBLE SMITH.—On the 20th inst., at Queen Anne Street, W., Noble Smith, F.R.C.S.Edin., aged 59. Funeral at Kensal Green on Wednesday, at 3 o'clock, leaving the house at 2 o'clock. Friends kindly accept this intimation.

ROBINSON.—On July 23rd, at 17, Blenkarne Road, Wandsworth Common, Thomas Frederick, youngest son of T. W. Robinson, M.D., F.R.C.S., aged 60.

STOCKER.—On July 21st, at Cheltendale, Middle Road, Westbourne, Bournemouth, Henry Charlton Stocker, eldest son of the late James Stocker, M.R.C.S., of Guy's Hospital, aged 68.

WANKLYN.—On July 19th, at the Laboratory, New Malden, Surrey, Prof. James Alfred Wanklyn, M.R.C.S., aged 73.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, AUGUST 1, 1906. No. 5.

NOTES AND COMMENTS.

The Local Government Board Speaks Out.

THERE are many local authorities which, animated we trust by an enthusiasm for domestic economy, seek to subserve that end by the penny-wise-pound-foolish policy of cutting their medical officer's salary. Of such is the Corporation of Ashton-under-Lyne. Proceeding some months ago to appoint a medical officer of health to succeed the late Dr. Hughes, they fixed his salary at the princely sum of £80 a year, and elected Dr. Talent to the post. The Local Government Board, with commendable regard to the real interests of the town, refused to sanction the appointment on the ground that the salary was inadequate for the duties attaching to the post of medical officer to a place of the size of Ashton-under-Lyne. But the Corporation proved obdurate, and the matter is still hung up. It should be obvious to the most cheese-paring intellect that it is impossible for a salary of thirty shillings a week to expect an able and experienced man to pay all the attention which modern hygiene requires to a town such as Ashton. Solomon in all his wisdom would have been unequal to the task. Whether in consequence of not having a medical officer or not, an outbreak of small-pox is now playing through the town, whilst the Corporation is engaged in correspondence with the Local Government Board. We hope Mr. John Burns will stand to his guns.

Sir J. Sawyer and Diagnosis.

AT the annual meeting of the British Pharmaceutical Conference held at Birmingham last week the members were officially welcomed by the Lord Mayor at the Council House, Sir James Sawyer appearing as local representative of the medical profession, In his introductory speech Sir James Sawyer is reported to have said that "the medical profession had well-nigh perfected itself in the diagnosis of disease, and in the scientific knowledge of the precise conditions under which disease existed," but that it had to "recognise that it was the treatment of disease that was lagging behind." We confess to such astonishment at reading these remarks that we can only believe Sir James Sawyer to have been wrongly reported. No one will deny that the treatment of disease has not kept pace with improvement in means of diagnosis. and that it is still in an elementary and unsatisfactory condition. But to speak of diagnosis as "well-nigh perfect" is to use the language of hyperbole, and we cannot believe that any practising physician can have made any such statement.

A Horse of Quite Another Colour.

THE correspondent of a London evening newspaper, writing under the pen-title of "M.D.," puts a pertinent question regarding a recent action to recover damages from a medical man who had communicated scarlet fever to a patient. Reversing the parts of the drama, he asks what damages can be claimed for a medical man who takes an infectious disease from a patient? What is sauce for the goose should surely be sauce for the gander. But "M.D." is not content with merely throwing a brilliant idea into the arena of public discussion and leaving it to its fate. He supplies at the same time a legal principle of liability in the light of which the matter may be reasonably considered. "Where a medical man," he asks, "has undoubtedly caught, say, scarlet fever, from a patient, could the latter be sued for damages by the medical attendant under the Employers' Liability Act?" While we leave that legal nut for the lawyers to crack, it must be confessed that the prospect of thus turning the tables is somewhat alluring. Many of the claims entered against medical men are vexatious actions brought by men of straw, and fostered by speculative solicitors. Perhaps the Medical Defence Union will kindly consider the case of the medical man infected by a patient's syphilis, or scarlatina, or carbuncle, or what not.

The "Coleman Case."

LAST week the final scene in what has come to be known as the "Coleman Case," took place, when the principal members of the medical profession in Dublin waited on Dr. Coleman and presented him with a resolution signed by more than thirteen hundred of his professional brethren. The proceedings, which we report in another place, consisted in short speeches delivered by the Presidents of the Royal Colleges and a reply by Dr. Coleman. Not alone those who signed the resolution of sympathy, but also the entire body of medical men in Ireland, may be taken as sympathising with him in the grievous trial through which he has passed. We trust that, now the medical profession has made clear the esteem in which they hold Dr. Coleman's personal, as well as professional, character, those members of the

public who are only too ready to impute evil will refrain from attempts to besmirch one who has been justified by the verdict of judge, jury, and professional brethren.

LEADING ARTICLE.

SWEATING AND THE PUBLIC HEALTH.

OF the many branches that belong to medical science it would be hard to imagine one more essential to the general safety and progress of the community than that of public health. In season and out of season its activity is untiring, and it is ever covering fresh ground in its struggle towards the ideal of universal health if not of universal happiness. Looking back on past achievements, it may point proudly to lessened mortality and to increased longevity. With even greater self-congratulation can it boast of plague and cholera banished from the shores of the United Kingdom, and of typhus and small-pox fast disappearing into the same region of exile. In addition to direct tangible results, however, the public health is concerned with many things of a vastly diverse and manifold nature. To prevent preventible disease and death is its dominant end and aim. In following up that attempt it has to become acquainted with the life environment of all sorts and conditions of men, and to avail itself of all kinds of scientific and social knowledge. In the field of labour the services of the sanitarian are called into constant requisition. Inasmuch as the working-classes form the greater part of the population, their physical well-being and the national prosperity must necessarily be connected in the closest of bonds. Labour legislation aims at the regulation of the conditions of employment so as to maintain a proper standard of health. Scientific medicine is concerned with many matters, as, for instance, the length of working hours, the employment of children, sanitation of mines, workshops and factories, and the control of "dangerous" trades. It should be noted that the share of created wealth which goes to labour in the shape of wages is left by the State to be determined by natural economic laws. At the same time, it may be pointed out that improved wages have in nearly all cases been due to the concerted action of labour organisations. In sharp contrast to the fair wages of most industrial occupations where combination of the workers is an accomplished fact, may be set the pitiably inadequate pay of the disorganised and unorganisable host of persons who toil in their own homes. The tendency is for employers to cut down wages below subsistence rates, and the "sweated" toilers have to work unduly long hours, often under bad sanitary conditions, for pay that is scandalously unfair. The recent Sweated Industries Exhibition held in London showed that Hood's "Song of the Shirt" applies to-day to many a wretched seamstress, and that the greed of the sweater extends to many industries beyond shirt-making. With this state of affairs the medical profession is closely concerned. Medical practitioners visit the homes alike of rich and poor, and know as no other men know the inner life of the community. They realise that the conditions of sweated labour predispose to disease and premature death. Modern medicine recognises the supreme importance of the resistance of the individual to the inroads of disease. In the half-starved outworker resistance is feeble, and he offers a ready prey to many infections, such, for instance, as that of tuberculosis. It is not too much to say that a great proportion of the applicants to the dispensaries, hospitals and other medical charities of our towns are drawn from the sweated home-workers. The evil extends to the children, for they are often pressed into the service in order to make up the scanty weekly earnings. These things constitute a terrible indictment against society, and it is to be hoped that preventive medicine will enter an emphatic protest against the evil that is undermining the national life. The problem is difficult of solution, but that has been the case with many social abuses that have been successfully overcome. One of the best-informed serious attempts to to deal with the whole matter is the model Bill introduced by Mr. H. J. Tennant to amend the Factory and Workshop Act of 1901. It is impossible here to enter into a detailed discussion of the many excellent proposals contained therein. It may be stated generally, however, that it makes the employer responsible for the sanitary state of the outworkers' homes, and provides for inspection. It is obvious that Parliament will be chary of interfering with the house of the Englishman. In the case of factories and workshops, however, the State has asserted its right of control, and it is surely not illogical to seek to extend that supervision when the scene of the labour is shifted to the homes of the workers, for the public health must now be the object of supreme solicitude. In conclusion, we advise all who are interested in this important subject to make a careful study of Mr. Tennant's Bill.

NOTES ON CURRENT TOPICS.

The "Normyl" Treatment Again.

IN the *Daily Mail* of last Thursday appeared an article by the Rev. Hugh B. Chapman on the results of the first year's working of the "Normyl" treatment under the auspices of the Normyl Treatment Association, and as some remarks we made a little time ago were replied to by Mr. Chapman we feel that we must not allow his criticisms to go unanswered. We said at that time that it was "not easy to accept the statement of the Secretary that no pecuniary profit is obtained from the sale of the medicine." Considering that three guineas is charged for the "medicine" we were pretty safe in making that statement, and Mr. Chapman lets the cat out of the bag by saying that "we have always said that a royalty is paid to Mr. Hutton Dixon." Quite so; we do not assume that Mr. Chapman

himself is anything more than a benevolent clergyman, but that he and his Association are the cat's-paws of an astute tradesman is evident to observers as well versed in the ways of quackery as ourselves. Let us assure Mr. Chapman that we have seen a good dozen of these "treatments" for alcoholism brought out, flourish, and disappear with the regularity of the stars in their courses, and that without benevolent clergymen like himself and Canon Fleming the profits of their promoters would be considerably less than they are. During the past year Mr. Chapman tells us there have been 1,650 "treatments"—we presume he means 1,650 patients under treatment—and that "the failures *that are known to us* (the italics are our own) do not amount to as many as 8 per cent. of the total number of treatments." Surely serious criticism of figures thus presented is hardly called for. We know nothing of the "state on admission" of the persons treated, but we do know how human nature is liable to persuade itself that a "treatment" is necessary even if it is not very ill, and we also know from Mr. Chapman that in some 120 cases the treatment has failed within a year! And if Mr. Chapman knows of 120, how many more are there, we wonder, that he does not know of? Mr. Chapman defends the principle of secrecy with regard to this remedy because he does not see "why the inventor should be asked to sacrifice the honourable results of his labour." But it seems to us that Mr. Chapman *does* see why he (Mr. Chapman) should sacrifice the honourable results of his own labour, as he is giving his services free in the cause of this treatment! Can he, we wonder, apply the argument? And is it too late for him to see the force of its application?

Forceps in the Abdomen.

Some two or three years ago a great outcry was raised because a well-known surgeon, after a long and tedious operation, had left a pair of artery forceps in the abdominal cavity of a patient. The accident is one which, theoretically, never should occur, but while human nature remains fallible it is to be feared that it cannot reasonably be expected that it will not happen again, any more than that no railway train will ever come to grief or that no motor-'bus brake will ever fail to act. But serious as is the overlooking of a pair of forceps, the occurrence does not always, or even necessarily, lead to a fatal termination. A case has recently been reported from Perth, West Australia, which strikingly illustrates the possible harmlessness of such an accident. A woman who complained of certain abdominal symptoms was thought by her medical adviser to have an abdominal tumour, but when she was examined by Rontgen Rays what appeared to be a pair of scissors was seen in the site of the swelling. The abdomen was therefore opened, and to the astonishment of the surgeon a pair of artery forceps which must have been there for eleven years was discovered. The forceps were removed, the abdomen closed, and according to the last report the woman was out of danger and making good progress towards recovery. This case shows then that the leaving of instruments in the abdomen is not such a serious accident as is popularly supposed, but it is nevertheless an occurrence that cannot be too carefully guarded against.

Snobbery in Army Nursing Service.

We have read in the *Army and Navy Gazette* certain charges of a grave character against the management of the Army Nursing Service as at present constituted, charges which even now we hesitate to accept without full evidence. The new Nursing Board, like all new brooms, it seems, wishes to sweep clean, and in the pursuit of this policy it has started by weeding out the old nurses. If the old nurses were bad, of course it would be impossible to say anything unless actual injustice were perpetrated; but it is stated in our contemporary that a young woman, although in every way a good nurse, was "hunted out" of the Service for no other reason than that her father was a non-commissioned officer. *The Army and Navy Gazette* says it can produce other and even more flagrant instances of this policy, and says that other nurses who have done good service at home and abroad have received their *conge* from the Nursing Board. The worst feature of the case is that the nurses seem to have no appeal and no means of redress; one nurse took her case before the High Court, but lost it, as no action can lie against the Crown. We feel sure that our contemporary would not make these statements without having satisfied itself as to their soundness, and we thoroughly agree with it that an impartial committee ought to be appointed to investigate these "reductions." In any case the nurses are likely to have the full support of the medical profession, which has suffered so much in the past from snobbery in the Army.

The Manufacture of Paupers.

We have preached for so many years in these columns on the text of hospital abuse that we may be permitted some satisfaction in observing that the matter is day by day attracting wider attention. Hospital "charity" administered to the undeserving is the very opposite of mercy; it curseth him who gives and him who takes. It robs the needy and deserving poor of the help intended for them; it robs the benefactors by diverting their gifts to improper uses; it robs a hard-working and ill-paid profession of their legitimate earnings; and it robs the recipient of his independence and energy. Our readers do not need to be told that in all the great cities of the Kingdom, but particularly in London, hospital administration has almost become a scandal by its carelessness in the discrimination of suitable objects of relief. It is satisfactory, however, to find that this knowledge is gradually permeating the public mind, since only from public pressure can we hope for reform. The *Spectator*, least sensational of papers, has recently devoted an article to the manufacture of

paupers by hospital relief, and we cannot do better than quote a sentence:—"There is a large body of thoughtful and experienced people who think that medical relief as it is now administered in London, more particularly through the out-patient and casualty departments of our voluntary hospitals, and through the free and part-pay dispensaries, is a frightful source of evil, inasmuch as it is to a large extent a waste of energy and material, and is a means of pauperising the recipients."

The Newspaper Press and Quackery.

ON another page we print the judgment of the Scotch Court of Appeal in the "Bile Beans" case. None of our medical readers can need any more light upon the subject, and we give the news for the benefit of our lay contemporaries. Not a single English newspaper has published any notice of the case, much less any comment upon it. Almost without exception they have had a share of the fabulous sums which were shown at the first trial to have been expended during the past few years in advertising "Bile Beans." The newspaper press, from *The Times* downwards, is showing that where consideration for the welfare of the public clashes with their sordid interests the latter are to be preferred. That the distinguished and wealthy proprietors of great London journals—they include at least three peers of the realm and several baronets—should, for the sake of gain, lend themselves to a discreditable traffic is deplorable. When the whole hideous story of the cruelty and fraud of medical quackery is disclosed to the world, a proper share of the shame and the blame will surely fall upon the noblemen and gentlemen who own the newspapers by the help of which the quacks find their victims.

The Management of Lunatic Asylums in Ireland.

As was to be expected, the Chief Secretary for Ireland was attacked by several Members in the House of Commons on Thursday last on account of the action of the Local Government Board, to which we alluded at length in our last issue. As we read the speeches of these gentlemen we fail to see that any reason for taking and handing the control of Irish asylums from the Medical Superintendent over to the Chief Clerk was brought forward, save the plea that the committees of certain asylums desired the change. We have, on the other hand, nothing but praise for Mr. Bryce's reply, which was as follows:—"Mr. Cogan has presented a totally different view of the Richmond Asylum dispute from that within my own knowledge. I myself intervened in the matter, and a compromise was effected on all but one point. It was an important point of principle—namely, whether the responsible officer of the Asylum should be the Clerk or the Resident Medical Superintendent. The Board thought it should be the latter, while the Richmond Committee held that it should be the Clerk. Medical opinion supported the Board's view, as did the large majority of the Asylums Committees in Ireland. I myself believed that the Board had done right." It will thus be seen that Mr. Bryce's speech entirely supports the statements made in the "special article" which we published last week on this important subject.

Channel Swimming.

THE channel swimming season has set in with its usual severity. The arm of the ocean, so dear to adherents of the blue-water school, which separates Great Britain from her nearest ally, is dotted with seekers after immortality, and the London Strand is dotted with placards describing their adventures. If Englishmen, as a rule, take their pleasures sadly, there are a few at least who take them strenuously enough to please even President Roosevelt. The medical philosopher cannot help asking himself what effect this Channel ploughing enthusiasm has on the health of those individuals who indulge in it at the moment, and of those who may be stimulated to do likewise in the future. Given a man of well-knit frame, sound organs, and long training by sea and land, it is just possible that he may come through the ordeal of an eighteen or twenty-four hours' swim without permanent damage; but such cases must be exceptional. Apart from the immediate dangers attaching to conditions of fatigue and chill, there is the other and greater one of life-long impairment of vital organs. The continued congestion of the viscera, produced through the chilling of the body-surface by sea-water is liable to produce insidious structural change in the kidney, and the violent muscular exertion of swimming without rest for many hours cannot but strain the heart terribly. We are prepared to congratulate the first successful emulator of Captain Webb's feat, but rather on the score of his pluck than his prudence. And to any who may be contemplating the task we would proffer the advice given by a contemporary to readers about to embark on a less perilous, but more commonplace undertaking—"Don't."

The Eton Slouch.

IN a recent volunteer inspection address at Eton College, General Oliphant took the boys to task for their "slouching" gait. What with one general preaching conscription and another universal drill, it looks as if the whole nation were slipping under the iron heel of militarism. When soldiers try to force their foolish ideas as to smartness of bodily carriage upon our schoolboys, it is indeed time for medical protest. Briefly put, the puffed-out chest and the stiffness of gait suggestive of a ramrod down the back are grotesque, unscientific, and defiant of the laws of common-sense no less than of physiology. The well-built athlete has a slight forward curve in the neck and the upper part of the back, and his chest is flat rather than otherwise, especially when not under strong exertion. May Heaven forefend that our public schoolboys, who are for the most part in

the pink of training and bodily activity, should ever be brought to regard the martial strut as a better way of walking than their own free and easy, but withal graceful, slouch! It is all very well for soldiers to assume a swagger as if they were the salt of the earth. They may be excused the assumption as members of a profession that cultivates blind obedience to discipline at the expense of individual initiative and energy. The plain unassuming public schoolboy has, happily, a way of slouching into control of the world's affairs in all directions, intellectual or physical, in a field that extends far beyond the range of the small section of the community that constitutes the British Army.

"The Redemption of the Inebriate."

In our leading articles of May 23rd and July 4th we described and analysed the series of puffs of the Keeley Institute headed, "The Redemption of the Inebriate," which during the past few months has been published in *The Times*. This examination was not necessary for medical readers. None of these could fail to recognise what were the real claims to consideration possessed by this philanthropic institution where patients are received only on payment of twenty-four guineas in advance for four weeks' treatment. We clearly explained several chief reasons, each sufficient in itself, and suggested many minor ones why these advertisements ought never to have been printed in such a form, bearing the endorsement of the leading journal; and particularly we pointed out that the puffs constituted a gross reflection upon our profession. These full explanations were given for the benefit of the proprietors and managers of *The Times*. We were willing to suppose that these gentlemen were not aware of the character of the business in which they were assisting; and we hoped that, being informed, they might withdraw from it. The series of puffs has, however, been continued. One is printed in the issue of July 25th, and we are promised another in August. We are told further that "The observations and conclusions of the independent medical practitioner engaged upon this investigation will form the subject of the next announcement." This announcement will be awaited with some special interest, since the name of the independent medical practitioner will then, no doubt, be disclosed for the information of the profession and the General Medical Council.

The Cardiff Asylum's Appointment.

On July 25th the Cardiff City Council met for the second time to consider the appointment of a medical superintendent for their asylum. The circumstances attending the first meeting have been already commented on in our columns, and were the subject of much local feeling. After interviewing the candidates, the Council proceeded to the election, and Dr. Goodall, superintendent of the Carmarthen Asylum, was chosen for the post. It is significant that Dr. Goodall's name was not on the "short list" at the previous meeting, and the protests that were entered at the time seem to have been fully justified.

PERSONAL.

Dr. Robert Jones, president-elect of the Medico-Psychological Association of Great Britain and Ireland, entertained the council of the Association at dinner at the Reform Club on July 25th

Dr. Emil Fischer, Professor of Chemistry in the University of Berlin, was presented with the honorary degree of D.Sc. at Manchester last Saturday. Professor Fischer's researches on the synthesis of the sugars and of proteids has placed him in the front rank of scientific investigators in Europe.

The name of Dr. Muir Smith has been added to the commission of peace for the borough of Eastbourne. Dr. Muir Smith is a well-known supporter of the Liberal cause in his neighourhood.

Mr. C. K. Darnell, of Bangor, was presented on July 17th, with a piece of silver plate, a congratulatory address, and a cheque for three hundred guineas by a number of medical sympathisers.

A number of his admirers are arranging to present Sir Henry D. Littlejohn with his portrait. Many of Sir Henry's old pupils will doubtless be glad of the opportunity of subscribing.

Lieut.-Colonel Skinner, Secretary to the Advisory and Nursing Boards at the War Office, has had the decoration of the Fourth Class of the Royal Victorian Order conferred on him.

Mr. Charles A. Ballance, of St. Thomas's Hospital, has also been appointed a member of the Royal Victorian Order.

It is with great regret that we record the death of Dr. Brouardel, perhaps the best-known French medical publicist.

By the death of Mr. Beit the London University Hospital of Medical Sciences becomes entitled to a legacy of £25,000. By the same event the King's Hospital Fund and Guy's Hospital both benefit to the extent of £20,000.

The will of Dr. James Steward, of Castlerock, Londonderry, and of Ballarat, Australia, has been sworn at £135,604. Dr. Steward left the princely sum of £50,000 to be divided among the Irish and Australian charities.

The first number of the most important work on birds that has appeared for many years has just been issued. It is entitled "The Birds of the British Islands," and is written by Mr. Charles Stonham, C.M.G., F.R.C.S., of Westminster Hospital.

In the list of new officers of the Legion of Honour published last week, the name appears of the Hon. Alan Percy Molyneux Herbert, M.D., uncle of the Earl of Carnarvon, and one of the oldest and most respected members of the English colony in Paris.

The medical officer of health for Birmingham told the Chemists' Conference in that city that out of twenty-seven samples of camphorated oil bought for analysis thirteen were more or less adulterated; and one sample of seidlitz powder "guaranteed to be pure contained only one third of the right amount of Rochelle salt.

A CLINICAL LECTURE
ON THE
TRANSMISSION OF SYPHILIS TO THE THIRD GENERATION.

By JONATHAN HUTCHINSON, LL.D.Oxon., Hon.M.D.Dub., F.R.C.S., F.R.S.,
Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and Royal London Ophthalmic Hospital.

GENTLEMEN,—The subject of my lecture to-day is the question of the possibility of the transmission of syphilis to the third generation. There is often a little misconception as to what is meant by the second and third generation, and I think we shall avoid that best by speaking of first heredity and second heredity. The facts as regards first heredity are well known, well established. So recently as the time of John Hunter, it was not believed that syphilis could be transmitted to the offspring. That view was held by some, and an opposite view by others, but many of the acutest thinkers on the subject were sceptical as to whether syphilis could be transmitted to children at all. None of us has any doubt upon the subject now. We know that a certain number of children, born of syphilitic parents, inherit the disease and manifest it in very well-known ways. It may be well to examine a little as to the fact of that inheritance, before we come to discuss the question as to whether there can be any second inheritance.

I think there is very great justification for believing that recently the parasite which causes syphilis has been discovered. That discovery merely gives to us increased demonstration of what we formerly believed. We have inferred, within the last half century, that there must be a specific living parasite which causes syphilis, just as we know there is a specific organism for small-pox, and another for measles, and so forth. And we have got so far as this: We have collected evidence as to the duration of the life of this specific vital organism which gives rise to syphilis, and have come to the conclusion that within two years after having been infected by it—probably within a much shorter period, even within two months—most patients who have contracted syphilis are free from the disease, in the sense of being liable to infect anyone else in any way whatever, and that there is then no danger of their producing syphilitic children. For instance, some fifty years ago a man was allowed to marry as soon as the secondary symptoms had completely disappeared—two or three months after having contracted syphilis—as it was at that time believed by most medical men that such a person was not liable to infect his wife or to produce syphilitic children. Since then we have learned that syphilitic infection may certainly extend over nearly two years. The possibility of a man infecting his offspring or his wife, or both, may last for that time. The spirochæte may live in his blood during a period of two years, and so long as it is living in his blood so long may he transmit that spirochæte to anyone, whether by inoculation or by contact. In order to determine whether the spirochæte is still living in the blood of a patient, you must examine the syphilitic lesions of either primary or secondary syphilis.

If you examine the patient in the tertiary stage of syphilis he is still liable to certain symptoms which result from the presence of the spirochæte previously, but which are totally different from those produced by its actual presence. We will say, then, that there is good evidence for believing two years to be the limit of the life duration of this syphilitic parasite. I have for long been accustomed to allow patients to marry at the end of two full years, irrespective of what their symptoms may have been, whether slight, or severe, or still persisting, or not. If, at the end of two years, a patient is still under treatment for syphilis, I should be still more confident that he could not infect his wife or transmit the disease to his children. I have let hundreds of such patients marry, and they have never come back to me in consequence of having infected their wives, or of having syphilitic children. If there were any cases in which they were disappointed with my advice I did not hear any complaints, excepting, perhaps, in one or two instances, and, as I say, these are exceedingly rare. So that I think I am justified in saying that the average duration of the contagious period of syphilis is about two years. This has a very important bearing on the question as to the possibility of the transmission of syphilis to the third generation, because a period of about twenty years must elapse before a child of syphilitic parents becomes a parent himself, or herself.

But there is another kind of evidence which we have investigated with great interest, evidence as to the events which happen to the children of parents who have married too soon—say, within the first year after one or the other, or both of them, had contracted the disease, or six months before the parasite had died in the blood. We have collected a very large amount of evidence as to that, and we know that if a syphilitic patient marries within the dangerous period and syphilitic children are born, then the first, and perhaps the second and third and fourth earliest births may suffer from the disease, but the later members of the family, if it numbers six, or eight, or ten children, are perfectly free from taint and show no evidence of infection. Many family histories of that kind have been published.

I would introduce a little matter of detail here and say that there are cases in which three or four first-born members of a family suffer from syphilis, and the family history gives a considerable number of abortions as having occurred. This will be regarded by some authorities as proof that the possibility of begetting syphilitic children lasts much longer than I am implying. There are, however, plenty of cases in which the first-born, and perhaps the second, suffer from syphilis, but, it is not inherited syphilis; it is the disease in its

Lecture delivered at the London Hospital, June 12, 1906, being the first of a series of four lectures to appear consecutively in this Journal.

acquired form, and the definite and ordinary symptoms of inherited syphilis are quite distinct from those which are present when the disease has been acquired. So that I think we are justified in believing that the period during which syphilis may be transmitted to children of the first generation is a comparatively short one.

But I believe that it makes a considerable difference as to whether the syphilis is inherited from the father or the mother. There is no doubt whatever that syphilis may be inherited from one or the other parent, but, in English practice, the great majority of cases of infantile syphilis are of paternal inheritance. Comparatively seldom do we meet with cases in which the mother was the one who suffered from syphilis. But I believe that the possibility of transmission lies very much longer in the woman than in the man. If a woman has had syphilis, the virus may be stored up in her ovary very much longer than it is likely to remain in the semen of the man. Hence, whenever transmission of the disease occurs after a very considerable period subsequent to marriage, and in cases where alternate children may suffer from syphilis, it is almost always the mother from whom the disease has been inherited. The paternal inheritance does not last long; a year or two is the limit of it, and, afterwards, provided that the woman is not affected with the disease, the children born are free from all taint.

It is said, especially by some French authorities, that syphilis in transmission is not always what they call virulent syphilis—that is, syphilis in which the child is sloughing and has the characteristic rash and other symptoms of pronounced syphilis; but the child inherits some sort of debility, or what is now termed dystrophy—some derangement in the nutrition of some part of the body, due to syphilis but not exactly syphilis. This French school speak of these dystrophies as presenting a great variety of symptoms, including rickets, deafness, deformities of the eye, club-foot, and even harelip. My own belief is that there is no reasonable probability that the majority of what are called dystrophies have any connection at all with syphilis, but that they occur quite accidentally and are just as common in populations into which no syphilis has ever been introduced as they are elsewhere. I believe that syphilis produces itself, or produces nothing. If the disease is transmitted the child must have its rash and infantile symptoms, and these symptoms, however slight or severe, must occur within three months of life. These are cases in which we must suppose that the specific spirochæte has actually gained access to the child's tissues, that the child has inherited the spirochæte and all that that organism is capable of doing. Either the spirochæte is present or else there are no symptoms; and, as I have already said, I do not believe that the tertiary symptoms, those symptoms which may be present after the spirochæte has perished, are capable of being transmitted.

I am going to discuss the probability of secondary inheritance. But we have, first, to ask, What are the conditions of primary inheritance? Primary inheritance is, after all, a very limited thing; it lasts a very short time. Is it in the least probable, then, the conditions of primary inheritance of syphilis having died out, that the disease will recur after any prolonged period? In most of the cases in which it is asserted that parents who had suffered from inheritance caused the disease to be inherited again, the evidence goes to show that the symptoms upon which the observer relied, in the secondary inheritance, were the ordinary ones; the child was born having snuffles and the ordinary phenomena. Now, if two parents, having both had syphilis, cannot transmit it over a period of a year or two, is it likely that the disease will show itself in their children ten or twenty years afterwards? I want to say it is improbable in the highest degree that such a thing should happen. Of course, improbability is not impossibility and does not disprove the fact; but when improbability is exceedingly great, then we have to look at the evidence and scrutinise it carefully before we allow our minds to relapse into a position of credibility. I think it is exceedingly improbable that there should be any secondary inheritance of syphilis, because the parents are then at a very distant period from the acquisition of the virus, and the virus does not last long. Supposing, however, that a patient, now an adult, had, as an infant, inherited the disease from his parents, and that he still possessed the virus in his blood, might he not transmit it by a scratch or accidental inoculation? We get no cases at all of supposed accidental inoculation from those who are the subjects of inheritance. But there is an interesting point in connection with vaccination. It is perfectly possible to transmit the virus in the circulation, and for that purpose a few blood corpuscles, taken from a patient who has the virus, would be quite sufficient. We have investigated a certain number of cases in which a series of children, a batch of fourteen or fifteen, inoculated from the same patient, all acquired syphilis. But all the cases in which that has occurred are cases of vaccination from an infant who has had syphilis, and not from older patients; and they were cases of arm to arm vaccination direct. Moreover, I never heard of an accidental case of syphilis attributed to contact with a subject of inherited syphilis, after the infantile period. If, in adult life, people who had as infants inherited syphilis were virulent subjects of the disease we should have syphilis very much more common than it is. That, again, is very strong evidence in favour of the belief that a patient who has grown up to adult life, and had syphilis in his infancy, is no longer the subject of the disease in its transmitable form. He is liable to keratitis, but it is a mistake to think that a patient still has the virus in his body if he can get an acute attack of keratitis. I hope that very soon, by experiments of inoculation, we shall be able to show quite definitely that, at the age when patients suffer from keratitis, they are not infective at all as regards the transmission of syphilis. All the evidence that we have at present on the point goes to prove that keratitis occurs after the syphilitic virus has ceased to be present, and is merely a consequence of what the virus has done to the cornea.

Now we come to the examination of evidence which has sufficed to convince many excellent observers that secondary inheritance does occur, and a number of cases have been collected as proof that even third inheritance of the disease may take place. These cases must, I submit, be investigated with much circumspection, or else they will not carry conviction. Nothing

amazes me more than to read statements published on the Continent, especially in France and Russia, as to the great number of cases which medical men there have seen illustrating this and that fact. I have been on the careful look-out for at least half a century, and have been in a position where my friends would, I am perfectly certain, have sent me any rather exceptional cases which appeared to refute the views that I am expressing to you now. As they have not done so, I must infer that they have no personal knowledge of any case having occurred illustrating the transmission of syphilis to the second inheritance. Therefore, I cannot see how these cases reported on the Continent can be cases of secondary syphilis. I could count upon my fingers the cases I have collected which were supposed to be cases of secondary inheritance.

It will be valuable, I think, just to go into a little detail as to cases that I have published of women, all of whom had inherited syphilis, but were, nevertheless, the mothers of healthy children. In one case the woman was forty-seven years of age, and was very evidently herself suffering from taint. She had six children, but none of these children suffered from any syphilitic symptom whatever. They appeared to be quite healthy, with the exception of one child who was the subject of a diseased hip. This affection would be claimed as a dystrophy in connection with inherited syphilis; but is there any probability that a diseased hip in a child had any special connection with inheritance from a mother who had suffered from syphilis?

Another case is that of a woman who informed me that she had three healthy children, and that none of them had ever suffered in infancy. I had no opportunity of seeing that they were perfectly healthy, but this woman was transferred to me by a colleague as being an interesting example of the results of inherited syphilis. She had a sunken nose and other characteristic symptoms of syphilitic taint.

Another mother who had suffered from inherited syphilis had a large family of children, but none of them had suffered from the disease, though several of them were delicate. There again are dystrophies, if you like, but there are plenty of delicate children who have not had syphilis. This woman's husband had died of decline, and there you have an obvious reason why her children might be delicate, without their having inherited any syphilis from her.

In another case a woman who had inherited the disease was the mother of children, none of whom had any inherited symptoms.

Now for two cases which looked as if there was inheritance. A woman came to me at the hospital, on July 22nd, 1862. She was obviously a subject of inherited taint, and had come to the hospital suffering from an attack of interstitial keratitis. She was married and had one child, and told me it was perfectly healthy. She brought the child, and on examination I found that it was very obviously suffering from syphilis. This was not a case of dystrophy; the child had snuffles and rash. I asked the mother whether she had had syphilis within the last two years, and she said she knew nothing of having contracted syphilis at all. I got her to send her husband up, and I asked him if he had suffered from syphilis. He said he believed he had had the disease. Though I could not write down definite proof that this man had been a subject of syphilis, yet I think it is exceedingly probable he had. There are many people who contract syphilis before marriage, and it is very possible that this man might have had it.

In my next case the evidence showed that the patient had really inherited secondary syphilis. In that instance a woman brought her child to the Polyclinic, for demonstration, as a subject of inherited syphilis. The case was unquestionably one of syphilis, all the ordinary symptoms being present. I also examined the mother, and there was no doubt that she herself had suffered in infancy from inherited syphilis. I asked to see her husband, and on being questioned, he denied having had syphilis. There was nothing about him which would justify my saying that I did not believe his testimony. The woman entirely denied having suffered from any symptoms during her married life. I said to the woman, "I wish you would come up to my house, and let me examine you further." She did so next day, and then, when I asked her if she had had any eruption the truth came out. She said, "Yes, I attended University College Hospital for sores soon after my marriage." "How long after?" "Several months." On asking what medicine she was given there, she said that they gave her pills for three months, soon after her marriage. There you see the fallacy at once. The probability is exceedingly great, amounting practically to a certainty, that this woman had been infected with syphilis by her husband. So that there was no proof whatever that the attack of syphilis from which this woman's child suffered was a case of transmission of the disease to the third generation. These are fallacies which attend almost all cases that are supposed to have inherited secondary syphilis.

I have an interesting paper by Dr. Marshall, a very able man, who accepts evidence that I should be very unwilling to consider conclusive, on the question of the transmission of syphilis to the third generation. He publishes one case in which he did not examine the whole data as regards the parents. Of what real value can such evidence be? In regard to other cases he has invented, the term, "binary syphilis," meaning thereby that a patient inherits syphilis, and then contracts it on his own account. I have no doubt that a patient who has inherited syphilis may contract it, but I maintain that a patient who transmits the disease to the second generation is not transmitting what he has inherited but what he has acquired. And although, usually, it is the mother who transmits syphilis, it is possibly not the mother who acquires it. As to binary syphilis, my experience does not give me half a dozen cases that could be considered binary; and I have most diligently collected examples of syphilis as having been contracted by those who inherited it.

Some very curious conclusions have been formed with regard to binary syphilis. For instance, Trenan believes that binary syphilis is one of the principal causes of the rapid degeneration of the population in country districts. How syphilis can be fatal to the population without, first, infecting individuals, it puzzles me to see. The influence of syphilis on the population generally is very small; it is not the cause of degeneration at all.

To my mind, such a thing as secondary syphilis rests upon an extreme improbability, and upon the extreme uselessness of the evidence by which its occurrence is asserted. I think it will be scarcely possible to record a single case free from fallacies, and I am therefore an entire disbeliever in what is termed secondary syphilis.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Jonathan Hutchinson, LL.D., Oxon. and Cantab., Hon. M.D. Dub., F.R.C.S. Eng., F.R.S, Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and the Royal London Ophthalmic Hospital, on "The Connection between Tuberculosis and Syphilis," delivered at the London Hospital,*

ORIGINAL PAPERS.

MITIN IN SKIN DISEASES.

By PROFESSOR E. SCHWARZ, M.D.,
Professor of Skin Diseases, University of Prague.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

At the last meeting of the Medical Society, Schwarz praised the efficacy of Mitin, recently introduced to the profession by Dr. Jessner and widely advertised by Prof. Nevinny. Whatever may be its future, specailists seem to be pleased with present results. Properly speaking, the unguentum base is an emulsion and not an ointment.

Schwarz said this was a new base for applying any drug to the cutaneous surface, and was therefore of incalculable value to the dermatologist. Hitherto our bases have all been composed of some form of fat from animals or plants but more recently from some inorganic substances such as shale, and may be enumerated as follow :—

Pigs Fat = Adeps Suillis	Vasogen.
Sheep skin = sebum Ovile.	Ung. Caseini
Wool fat = Adeps Lanæ or Lanolin.	Ung. Glycerini
Vaselin, Hitherto the best.	Ung. Leniens
Ung. Paraffini, a mixture of hard and soft paraffin.	Resorbin. Fetron, etc.

All these agents have now long been in use and each has its defects and merits from a scientific point of view, although each manufacturer has endeavoured to reduce the latter to a minimum. All these bodies have two defects to surmount—viz., either the constituents of the base are chemically unsuitable or the surface of the skin is too sensitive—*i.e.*, idiosyncrasy is too great for any external application. The fat of animals is excellent when rubbed in fresh, but becomes an irritant when rancid. Here the inorganic fats have the advantage, as the paraffins and vaselines do not decompose in this way, but their chemical constituents are again injurious to many skins that make them inapplicable ; hence the one is objectionable from its decomposition, the other from its chemical composition.

There is another property in a base that should not be overlooked—viz., its capacity for taking up any drug and distributing it regularly throughout its substance. If it does not admit of the drug being regularly divided, its use as a vehicle is dangerous. Its consistence is another important property of an ointment, and in this respect vaseline and resorbin have met with approbation ; but both have been objected to on the ground of acidity, as both have varying quantities.

Schwarz asks what a proper vehicle should possess ? First it should be neutral, free from all irritants, consistent, retain the drug evenly, while it preserves the skin in a normal functional condition.

The sweat and fat glands provide secretions of great importance in retaining the skin in a normal condition—the first being a serous fluid, the latter a fatty product ; the former for regulating the heat of the body, while the latter softens the skin and covers it with a protective shield in case of poisons or injury, giving an elastic consistence to the cutaneous surface after being bathed with perspiration. There is also another consideration to be borne in mind with regard to the lymph serum, which dermatologists value according to the intensity of the disease. There are other properties of equal importance, viz., suppleness of the skin and smell of an ointment, on which a patient often places value according to his sensibility ; and, lastly, the base should be miscible with other substances to make it effectual as a healing agent.

These were the points discussed with Jessner in his ointment preparation of Mitin. His first combination was with lanolin, glycerine, water and egg, in the form of emulsion, with other fats. He found a pure emulsion would not serve his purpose as the fat tended to separate from the water and rendered the application useless as a vehicle for presenting other substances to the skin. He subsequently resorted to the principle of superfatting the base with more success after a series of laboratory experiments. As milk was a product of the cutaneous glands analagous in many respects to the sebaceous product, he thought this principle ought not to be forgotten and hence obtained a product superfatted containing a large amount of fluid similar to serum.

This preparation is now manufactured in three forms—viz., mitinum purum, cosmeticum and paste. The first is combined with mercury, the properties of which have impelled me to trouble you with such a complex article of the pharmacopeia. Mitinum purum is a white, soft, inodourless neutral substance easily miscible with any other medicament, and when desirable 30 per cent. of oil may be added. To the dermatologist it is a great boon where the skin is red, broken or tender ; its action is soothing and comforting to the cutaneous surface. The mitinum cosmeticum contains more emulsified fat and serum, which fits it for a general sedative and may be slightly perfumed for this service. This paste is admirably fitted for the protection of abraded surfaces or mixing with any other substance for giving relief, such as resorcin, &c. This property has already become so stereotyped that a 15 per cent. Lenigalol paste is largely sold for general use. The practical point I alluded to was the efficacy of the mercurial preparation which is sold in 35 gramme graduated tubes. It contains 33⅓ per-cent. of mercury or 10½ grammes in each tube.

The following 25 cases were treated with mitin in one or other of the forms described (*a*) Four eczema, two healed, one improved, and one unchanged ; (*b*) one with dermatitis (Dühring) cured ; (*c*) six with acne vulgaris still under treatment ; (*d*) thirteen from Lues—two primary, eight secondary, three tertiary ; (*e*) one from Herpes zoster.

The unhealed eczema case was an obstinate surface in the armpit always bathed in perspiration, with itching and thick infiltrated raw dermis. The mitin relieved the raw surface, but owing to the itching and scratching thigenol had to be added to the paste before a cure was effected. The two cured were in the desquamating stage and yielded readily. The remaining case, a female, æt. 45, had first a discharge from the ear, which finally infected the entire body and brought the patient to death's door from the want of rest. The Mons Veneris and inguinal region were in a raw desquamating state which had become chronic. Mitin purum, generous diet, and tincture of iron was prescribed with immediate improvement. The skin is now soft and flexible, of a normal colour, without any trace of itching after eight applications of pure mitin. After two years' suffering she now sleeps and eats well.

The six acne cases were treated with cosmeticum, which was followed by a removal of the comedo. It may be noted here that mitin seemed to act as a protection against further infection. The Herpes zoster: though containing cocain the ointment failed to counteract the raw painful surface on the right side of the head.

The Dermatitis herpetiformis of Dühring requires a more detailed description. In December last H. J., æt. 50, married, and a gardener by trade, came to hospital complaining of an intolerable itching which had afflicted him for three years; otherwise he seemed to enjoy good health. On the neck and hairy parts, as well as the extremities, small white vesicles appeared with great itching, causing him to rub the surface, which became inflamed, the hair forming a hard mass. The internal organs were perfectly healthy. The back and neck were thick, raw-looking, and bleeding in parts from the constant scratching. There was a good deal of pigmentation from the long duration. After seven days' treatment the patient was greatly relieved and the red thickening had disappeared. The mitin was continued, but no new vesicles appearing the patient was discharged. Reports confirm a perfect cure.

The syphilitic cases were all treated with mercurial mitin. The first of the primary cases had a hard annular swelling with phymosis and large hard glands; the second resisted other forms of treatment. Both were put on two grammes daily local inunction with wonderful success.

The eight cases in the secondary stage had the exanthema papules in the throat and anus. Five grammes of mitinum mercuriale were applied daily. In the course of two weeks every symptom had disappeared.

In the three tertiary cases one of them suffered from a severe form of Psoriasis palmaris et plantaris; the second from a painful eruption on the breast; while the third suffered from a serpigenous ulcer on the roof of the mouth and uvula. All of them healed in a short time. In other cases of psoriasis warm bathing of the hands and feet hastened the absorption. It is scarcely necessary to praise the working of the mercurial preparations as all forms of mercury are effectual in syphilis, but the vehicle by which it is presented to the body often modifies its action and adds to the comfort of the patient. Mitin is readily absorbed and is clean. It is easily washed off without any loss of time and carefully put up in tubes of 30 grammes for immediate use, which enhances its value for practical application. One medical property which should not be forgotten by the dermatologist is its neutral quality as a necessary attribute in the healing process. Where hair is present it is easily cleaned away in inunctions and prevents folliculitis. It prevents the stomata from becoming choked and hastens the action of the drug.

In conclusion, we have obtained an ointment with all the properties so long desired by the dermatologist: to keep the skin elastic, readily absorbed, not greasy, clean, and easily removed.

HAY FEVER AND ITS TREATMENT.

By WILLIAM LLOYD, F.R.C.S.

Nose, Ear, and Throat Surgeon to the Kensington General Hospital: Aural and Laryngeal Surgeon to the St. Pancras and Northern Dispensary, &c.

THE most frequent type of periodic hay fever is that which occurs during the flowering of certain plants during late spring and summer, but some individuals suffer during any period of the year. During the warm and dry weather the atmosphere is naturally laden with a host of stimuli that do not exist in winter. Until recently this form of vasomotor coryza was believed to result from the action of the pollen of plants which, as experiments have shown, play an important rôle in the disease; but other equally important exciting causes which may induce an attack are—odours, emanations of animals, cats, dogs, horses, heat and irritating particles such as dust, ipecacuanha and the like.

It is generally accepted that there is essential to the development of vasa-motor catarrh the presence of three factors, which are classified as, first, a neuro'ic temperament; second, a hyperæsthetic condition of the terminal filaments of the sensory nerves, usually brought about by some local change; and third, the presence of some source of local irritation. The usual course of the malady is somewhat as follows. In a majority of cases like those of ordinary coryza, only that the initial chill and constitutional symptoms are absent. The victim, more frequently during the summer months, suddenly suffers from a feeling in the nose of being "stuffed up," followed by a thin, clear, serous discharge. The mucous membrane of the tear-ducts is swollen, causing lachrymation, itching in the eyes, and the conjunctivæ are infected. Violent paroxysms of sneezing repeat themselves again and again throughout the day. Exposure to direct sunlight or dust produces a paroxysm of sneezing. There is frequently a distressing cough, especially at night.

The amount of constitutional symptoms depends to a certain degree upon the severity of the attack. There is usually more or less irritability of the temper and other manifestations of extreme disturbances of the general nervous system. The patient becomes pale, and there is a general lowering of the physical tone, as shown by lack of vigour, incapacity for mental activity, impairment of the memory, and very low-spirited lassitude, loss of appetite, and marked disturbances of the digestive functions. Attacks become more and more severe with each recurrence, and after a few years the upper respiratory tract is involved. Asthma may develop so like as to be indistinguishable from the ordinary bronchial form. The asthma of hay fever exists by day as well as by night. Both affections may persist alternately all through the summer months.

On Examination of the Nose.

The victims of hay fever form two clinical types.

1. Some pathological condition of the nose and naso-pharynx—*e.g.*, adenoids, hypertrophic rhinitis, diseases of the sinuses, polypi, etc. These structural peculiarities associated with nasal catarrh render the mucous membrane inflamed and irritable, so that the mere touch with a probe may be sufficient to induce an attack.

2. The condition of the nasal mucous membrane. To rhinologists distinguishable as (*a*) The bright red appearance; (*b*) In cases of long standing has a sodden, pale appearance. The membrane is usually extremely sensitive throughout to the use of the probe, but certain areas only produce cough and sneezing. These areas, after a careful examination of a large number of cases, may be said to be confined in 90 per cent. of patients to the structures in the upper and anterior half of the nasal cavity—*e.g.*, middle turbinate and meatus, the region of the ethmoidal cells, and where the septum meets the nasal cartilages.

There may be only one tender spot or several or this hyperæsthetic condition may comprise a large area of the mucous membrane.

Treatment.

The fact that during the last few years so many different modes of treatment have been suggested points out very forcibly that hitherto there has been found no specific. This is not to be wondered at when we take into consideration that there is certainly more than one cause. As a matter of fact we may divide all cases of hay fever into two distinct groups.

1. Those in which there is some pathological cause, for the affection of a gross nature such as polypi, etc.

2. Those in which the interior of the nose appears to be normal, but that the mucous membrane is hypersensitive in certain areas, and when stimulated bring in a typical attack of hay fever.

Those in the first group are usually readily cured by removing the pathological condition and will not come within the scope of the present paper. It is those in Group 2 which give us so much trouble and form a veritable opprobrium of medicine. I wish to point out that these also are really amenable to treatment to a remarkable degree if the subject is approached in a scientific spirit.

It has been suggested for some years that the affection in these cases was of a reflex nature, the morbid impulses starting from some part of the mucous membrane of the nose, and in consequence many attempts have been made to cure this condition by the electro-cautery, chronic acid or some other application to what was supposed to be the offending area. The result has unfortunately usually been failure, mainly from the fact that the wrong spot was taken to be the starting point of the reflex arc. This spot was usually pitched upon from the fact that it was, or appeared to be, more tender than the rest of the mucous membrane. The parts usually cauterised have been the following:—Inferior turbinate, lower half of the septum, or perhaps some tender area over a spur. Careful investigation has convinced me, and the results of treatment have confirmed me in my belief, that hay fever is rarely the result of a morbid condition of those spots, but that the offending area is really confined to the upper and anterior half of the nasal cavity.

Speaking roughly, the essential part of treatment is the *hardening* and *destruction* of this hyperæsthetic area, which may be accomplished either by means of the cautery or by certain liquids of a caustic nature.

The refinements of cautery technique can only be learnt by experience, but there are certain principles which should be understood. Many operators are in the habit of treating the nose repeatedly with the electro-cautery or other escharotics instead of a thorough destruction of the hypertrophic tissues at a single application. This I believe to be bad practice as a rule in hypertrophic cases. It is not desirable to keep the nose continually irritated by repeated applications. In hyperæsthetic conditions where much surface must be treated it is necessary to make several applications, none of which should involve more than the mucous membrane. The application of escharotics is more painful and greater reaction follows.

I will briefly cite a few typical cases in which this treatment was successful.

Case I.—Mrs. S., æt. 27. Suffering for years and during all periods of the year. Violent paroxysms of sneezing on getting up in the morning accompanied with coryza. Well marked acne rosacea. *Examination of Nose.*—Hypertrophic rhinitis and catarrh. *Treatment*—Removal of posterior ends of inferior turbinates with Snare-Cautery and alkaline lotions.

Case II.—Mrs. W.—May be said to be an invalid through hay fever. Dust of any kind or exposure to sun brought on a typical attack. *Examination.*—The nose seemed normal but the mucous membrane presented a bright red appearance and extremely sensitive to the probe, with areas of sneezing. Deviation of septum to right. *Treatment.*—Electric cautery and chromic acid to sensitive areas on five occasions followed with a nasal spray of menthol and ol. eucalyptus in parvoline. I did not operate on the septum. The patient is now able to take every liberty and can expose herself to any of the stimuli that before treatment brought on the disease.

Case III.—Miss H., æt. 23. Hay fever for years. Commenced in July and continued until end of summer. *Examination*—Adenoids with hypertrophic rhinitis. *Treatment*—Removal of adenoids and posterior ends of inferior turbinates, Alkaline lotions used until the cut surface healed and the nose was clear of catarrh.

Case IV.—Mr. M., had been a victim to hay fever and asthma for nearly ten years. *Examination*—Nasal polypi and hypertrophic rhinitis. *Treatment*—Removal of polypi. The hyperæsthetic areas treated with the electro-cautery and trichloracetic acid.

I may state several of my patients have been treated with hay fever antitoxin and powder. In none of them did the remedy act, although some thought it gave them relief at first.

The general hygienic surroundings of the patient, his sanitation, as well as his physical regimen, should be carefully considered and regulated. The marked neurasthenic patients should be treated with tonics—iron, and strychnine.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Two Kinds of Valvular Heart Disease.

By LEONARD WILLIAMS, M.D., M.R.C.P.

THESE two patients illustrate what I have often spoken of here before, namely, that there are two kinds of valvular heart disease. The one kind, with which we are all so familiar, is due to endocarditis, which may, of course, be the result of rheumatic fever, scarlet fever, or other acute specific diseases; the other kind, upon which I have dwelt at considerable length here and elsewhere, is the result of high blood pressure, giving rise to arterio-sclerosis, degenerative aortitis, and, ultimately, to disease of the coronary vessels, narrowing of the aortic ring, and puckering of the valves.

It has been asserted that aortic regurgitation, when complicated with mitral regurgitation, is a very much more favourable disease from the prognostic point of view than aortic regurgitation pure and simple, and it is pointed out in explanation that the reflux through the aortic valves, having to meet the oncoming rush from the left auricle through the mitral valves, puts a strain upon the left ventricle which the latter is frequently unable to endure, unless the mitral valve also is incompetent. It is also said that digitalis, when given in a case which presents regurgitant disease at both valves, is far less dangerous than when given in regurgitant disease of the aortic valves alone, and the reason which is given in explanation of this undoubted fact is that digitalis prolongs the diastole. Now, digitalis undoubtedly does prolong the diastole, but it also has another effect which we are far too liable to lose sight of, namely, that it constricts the peripheral vessels and thereby increases the general blood pressure. To increase the general blood pressure in regurgitant disease of the aortic valves, which has been brought about by hypertension, is obviously to provide an increased burden to the already labouring heart, and I am strongly of opinion that the real explanation of the danger of this drug in this disease is due to the fact that it is so often administered without regard to the original cause of the valvular mischief.

The younger of these two patients, a man, æt. 25, gives us a definite history of rheumatic fever four years ago, and of chorea when he was a child. He has what is commonly called a see-saw murmur at the aortic cartilage, a very much enlarged heart (the *cor bovinum* of the text-books) and a water-hammer pulse.

The other patient is a man, æt. 48, but looks older than he is. He has never had rheumatic fever, or, indeed, any illness of a serious nature, but he has lived well, as it is called. You notice the injected capillaries in his face. On examining his heart you will find that the displacement of the apex beat is comparatively slight. He has dulness at the manubrium sterni, and a definite see-saw murmur at the aortic cartilage. Neither of these patients has any regurgitation at the mitral valve, and neither has any albumen in the urine. If the younger had such regurgitation it would mean that during his attacks of rheumatic fever or chorea, both the mitral and aortic valves had been implicated in the endo-cardial process. He is now very unlikely to develop regurgitation at the mitral valve until his heart dilates through progressive weakness of the myocardium, an event which may not happen for forty years.

The other patient, the older man, is on the contrary very likely at any time to develop a regurgitation at the mitral valve, for his systolic blood pressure is already 165 mm. of mercury, and the myocardium is not likely to be able to stand the strain of such pressure for very long. What happens in these cases is that the ventricle dilates, the mitral ring enlarges, and allows the blood to regurgitate into the left auricle. It is in effect a safety valve process.

Now, if we give digitalis to the younger patient provided that we keep him in bed, and give the drug in small doses, we shall do him no harm. If, however, we are foolish enough to overlook the cause of the aortic regurgitation in the case of the older man, and give him digitalis, we shall probably kill him, whether he is in bed or going about. To give digitalis, therefore, in a case of aortic regurgitation without satisfying yourself fully that the regurgitation has not been caused by, or is not associated with, high blood pressure, is to commit a therapeutic crime. If high blood pressure is present, the only way to treat these cases is to give them drugs such as iodide of potassium, which are calculated to reduce blood pressure, and to see to it that the patients' way of life, especially in the matter of meat foods and alcoholic drinks, is such as to assist the action of the iodides. There are far too many people who give digitalis to any patient who is found to be the subject of a cardiac murmur. That is always unnecessary, and is often very dangerous. As the French say, "Une lésion d'orifice n'est pas une maladie de cœur." Heart disease in this sense can be said to exist only when the myocardium fails and compensation is upset. It is then that digitalis does good, and not until then. To give the drug when the myocardium is acting well is to court disaster by interfering with that compensatory equilibrium which it should be our first care to maintain when present, and restore when absent.

OPERATING THEATRES.

CITY ORTHOPÆDIC HOSPITAL.

EXCISION OF HIP-JOINT FOR PATHOLOGICAL DISLOCATION AND SEPTIC INFECTION.—Mr. JACKSON CLARKE operated on a girl, æt. 6, who had been admitted some weeks previously with a sinus in the outer and upper part of the left thigh and a history of trouble in the corresponding hip-joint of three years' duration. She had been kept under observation in the wards for some weeks, the joint being irrigated through the sinus with 1-40 carbolic lotion, and the evening temperature varying from 1 to 3 above normal. The limb was in a position of adduction with marked shortening, due to displacement of the femoral head above the acetabulum. The child was in a weakened condition, being somewhat emaciated, and her appetite was poor, so Mr. Clarke decided that it was necessary to excise the joint. Operation: A posterior incision was made through the muscles on to the remains of the neck of the bone, which was divided near the inter-trochanteric plane; granulations were removed from the joint cavity by a flushing gouge; the connection of the old sinus with the joint cavity was traced, and the sinus well scraped and flushed; a drainage tube was put in the upper end of the incision and the child returned to bed, a Liston's long splint having been put on the sound side, and an extension of 5 lbs. weight applied to the limb, which had been operated upon, and which was now placed in a position of abduction. Instructions were given for the tube to be removed after twenty-four hours.

AMPUTATION AT THE HIP-JOINT FOR SEPTIC OSTEO-MYELITIS OF THE FEMUR INVOLVING THE HIP-JOINT.—The same surgeon operated on a boy, æt. 6, who had been sent up from the country as a case of hip-joint disease. The patient was in a condition of extreme illness, and was suffering acute pain; his temperature was typically "hectic," and his sleep was broken by spasms of pain which caused him to cry out. No thorough examination could be made until he had been placed under an anæsthetic, and then it was found (1) that there was grating in the hip-joint, and (2) that the lower epiphysis of the femur was separated.

The hip-joint was opened by the posterior incision, and a quantity of pus evacuated. When the cavity had been washed out, the incision was carried along the femur down to below the middle of the thigh, where it was continued down to the bone and the operation rapidly completed by freeing the bone, the muscular attachments being divided close to it. Hæmorrhage was controlled by an assistant grasping the flaps. The operation was then quickly completed in the usual way.

Mr. Clarke said, with regard to case 1, that it illustrated tuberculous disease of the hip-joint, in which conservative measures were inapplicable, and that for two reasons: (1) The presence of a dislocation; and (2) the complication of septic infection by way of the open sinus which had been left after evacuation of an abscess. When the disease is allowed to subside in a case of dislocation, the limb is usually in a very unsatisfactory position, there being considerable *real shortening* as well as a great degree of *virtual shortening* dependent on the adducted position; therefore, if excision was not done, some operation, generally osteotomy, was required in later life, meanwhile the patient was exposed to all the risks of active tuberculous disease, supposing the radical operation were not done. Had the case not been complicated by sepsis, Mr. Clarke said he would have used the anterior incision, but the latter would not have given the necessary facility of drainage. With reference to case 2, Mr. Clarke remarked that the operation was called for as an urgency under circumstances which left no choice, the child having been sent up in such a condition as to make it unsafe to remove him to a general hospital. This case, he thought, thus illustrates the undesirability of separating orthopædic work from general surgery, or, in other words, the chronic cases that constitute the bulk of what is known as orthopædic surgery at times assume acute phases which require wide surgical experience if they are to be adequately dealt with. As further comment on the operation selected in this case, he considered it was the one which gave rise to the least shock, and was most rapidly performed. Another advantage, he pointed out, was that it was, in his experience, less frequently followed by painful neuromata than the higher amputations. On examining the parts removed the interior of the whole of the shaft of the femur was found to be full of pus which extended into the space between the shaft and the epiphysis.

The enterprise of the Liverpool School of Tropical Medicine is exemplified by the issue of a report printed in French on the subject of malaria in the Congo. It is entitled "La Prophylaxie de la Malaria: Rapport de l'Expedition au Congo, 1903–5." In its fifty-eight pages is some exceedingly useful information dealing with the disease, and towards the stamping out of which the efforts of the School of Tropical Medicine are directed. The Government of the Congo Free State will, no doubt, find this volume, which is neatly bound, of immense utility.

At the last monthly meeting of the Belfast Rural District Council a letter was read from the Local Government Board drawing the attention of the council to the exceptionally high death-rate in the country from pulmonary tuberculosis (consumption), and expressing the hope that in the interests of public health the Council would take such measures as were calculated to diminish the present high mortality from consumption in so far as their district was concerned.

TRANSACTIONS OF SOCIETIES.

THERAPEUTICAL SOCIETY.

Meeting Held July 14.

A general meeting of the Therapeutical Society was held on Saturday, July 14, in the Pharmacological Laboratory, Cambridge, at the invitation of W. E. Dixon, Esq., M.D., Assistant Professor of Pharmacology.

Sir Lauder Brunton, the President, was in the chair, and thirty-five Fellows and visitors attended the meeting.

Dr. W. E. Dixon showed the action of various drugs on the blood supply to the lungs of a pithed cat, demonstrating that adrenalin and ergot increased the amount of blood in the lungs. Squill produced slight congestion only, while Strophanthus somewhat diminished the amount of blood in the lungs.

Dr. G. S. Haynes demonstrated the action of Squill on the mammalian heart kept at a constant temperature, and perfused with normal saline solution for half an hour, and then with 1 in 2,500 solution of B.P. tinct. scillæ. This had an extraordinary powerful effect, increasing the force of the heart-beat at least tenfold in about one hour. Death occurred in systole in two hours.

Dr. G. S. Ricketts showed specimens and tracings proving that atheroma could be produced in rabbits by any substance which markedly augmented the blood pressure on injection into the circulation. This occurred especially with adrenalin, nicotin, tobacco, and squill. The rabbits were injected daily and killed after treatment for three weeks or three months. He also shewed microscopical specimens demonstrating the rupture of elastic fibres, and the deposition of calcium salts.

Dr. T. G. Slade demonstrated the action of muscle extract on plain and striped muscle proving that the extract after fatigue was more powerful than that obtained after rest. He also showed photographs of the ergograph, and the interesting results obtained by its means.

Dr. B. Hudson showed the action of physostigmine on the frog's heart, which was complicated as it acts on nerve cells, nerve endings, and muscles, and some interesting tracings throwing light on the vexed question of the action of nerve endings.

Dr. Horsey, of Toronto, showed aortæ of four foxhounds with atheromatous changes, also an apparatus for perfusing surviving organs.

After a tea, supplied by Dr. Dixon, the visitors went to the Botanical Gardens, and were shown round by the Curator R. Irwin Lynch, Esq., M.A., who exhibited many curious and medicinal plants, and explained their uses, and also an interesting collection of bog plants. Thirty-five of the Fellows and visitors then dined together in Downing College Hall, afterwards many returned to London, but eight remained in Downing College till Monday.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 28th, 1906.

The last number of the *Zeitschrift f. Beam.* has a paper on

Spontaneous Penetrating Rupture of the Heart.

by Dr. Kypke-Benchardi. Spontaneous ruptures of the heart are much less frequent than the traumatic. The case described was that of a man, æt. 58, who one day got up feeling unwell; at midday he had a light meal, after which he died suddenly. As both the brother and the wife of the individual charged each other with having poisoned him, a judicial *post mortem*

examination was made. This revealed no symptom of poisoning, but two lacerations in the left cavity, the larger being 7 cm. in length. This for a short distance had penetrated through the wall. The pericardium, which was uninjured, was filled with blood; the heart was strongly hypertrophied, and showed fatty degeneration of the muscular structures. The case fitted in well with others of its class, in which the muscles are so much changed, but little is required to bring about the rupture. It will be observed that the *post mortem* completely set aside any possibility of poisoning.

CHANGES IN THE SKIN IN PSEUDO-LEUKÆMIA.

A paper on this subject appears in the *Arch. f. Dermat. end Syph.*, 80-1, by Dr. P. Linser. A man, æt. 54, had a considerable number of tumours varying in size, about the face, neck and body. They sprang from the skin, but a part of them formed tumours reaching into the underlying muscular structures. The whole left lower arm and hand and part of the upper arm were thickened with elephantiasis. A portion of this excised and examined microscopically showed a round-celled infiltration penetrating into the muscular tissues without any orderly arrangement. The diagnosis was difficult; mycosis fungoides and multiple sarcoma were thought of. Examination of the blood gave the first correct indication; this showed a comparatively excessive increase of the leucocytes from 25 to 45-67 per cent. This, along with enlarged spleen and liver and inguinal and axillary glands, left no doubt that the case was one of pseudo-leukæmia with cutaneous tumours. As the patient, without any known cause, got an attack of pneumonia of the lower lobe of the right lung, the tumours and infiltration became markedly better, but after the cessation of the fever they quickly returned to their old condition. Death took place about two months after leaving hospital, the patient previously suffering from shortness of breath, perspiration, splitting headaches, and severe epistaxis. A few days before death the tumours suddenly disappeared. In a second case, that of a man, æt. 58, who had the same symptoms of pseudo-leukæmia (increase of leucocytes to 94 per cent.) enlargement of the liver, spleen and the superficial glands, the skin affection that accompanied the disease was an erythrodermia exfoliativa, the anatomical substratum of which was a lymphocyte infiltration of the skin through its whole thickness with œdema. The skin was thickened over the whole body, reddened and covered with scales. In this patient also an intercurrent attack of pneumonia took place, and another time an attack of bronchitis came on with high fever, and some weeks before death a regression of the skin infiltration took place. During the latter part of his life such an increase in the absolute number of leucocytes took place that one could say there was a transition from pseudo-leukæmia into true lymphatic leukæmia.

From his observations, the author adheres to the view of Pinkus, that the changes in the skin are not due to leucocytes coming from the blood, but that they are developed locally out of the traces of lymphatic tissue that are normally present in the skin.

A RECORD TEMPERATURE.

Dr. R. Heller reports a case of exceedingly high temperature in the *Munch. Med. Wochensch*, 23, 1906, the cause of which was unexplained. He speaks of it as the highest yet measured.

In a girls' institute the writer was called upon to treat several of the inmates for influenza. A girl, æt. 15, complained of general malaise, and showed a temperature of 37·3° C. In the afternoon the writer was sent for again, as the temperature had risen to 44° C. (about 112° F.); it was taken with four exactly-tested thermometers one after the other. Whether the temperature rose over 113 could not be known, as the instruments did not register above that figure. The pulse never reached beyond 120. The general condition was fairly good. Objectively, there were a commencing splenic tumour and a systolic cardiac murmur at the apex. After a few days the temperature became normal, and recovery took place.

THE SERUM TREATMENT OF SYPHILIS.

The *Archiv. f. Dermat. end Syph.*, 79, 1. contains a paper by Professors Risso and Cippolina, on the results obtained by treating syphilis, especially in its secondary and tertiary stage, with serum obtained from dogs, asses and goats. The animals were previously treated by the injection of blood from persons in the secondary stage of the disease, being injected subcutaneously and into the peritoneal cavity. With the serum, to which a small quantity of a solution of the blood corpuscles was added, thirty-four syphilitic patients were treated by injection into the muscles. The results obtained were good. Especially in the cachectic condition in the later stages of syphilis the results were excellent. Dog serum appears to be the most active, but it could not be borne long in the doses first given, but by lowering the dose, or by giving it every second day instead of every day, the disagreeable accompaniments were avoided. These were local pain, urticaria, swelling of the regionary glands, &c. The dose was 1 to 2 ccm.

AUSTRIA.

Vienna, July 28th, 1906.

RAYNAUD'S DISEASE.

AT the Gesellschaft Necker exhibited a boy, æt. 12, suffering from the disease known by the name of the clinicien who first differentiated it in 1862. It was found at a later date to consist of three stages (*a*) local asphyxia, (*b*) local syncope, and (*c*) gangrene. Whether the disease is vascular or neurotic is not easily affirmed at the present time.

The boy was pale, cold, and weakly looking. The skin was livid, thin, and corrugated, the hand having ridges with punctiform hæmorrhages. The right foot was minus the terminal phalanges of the second, third, and fifth toes. The stumps resembled an amputation with the exception of a small nail on the terminus. The same conditions existed on the second and fourth toes of the left foot. On the extensor side of the second toe and the flexor side of the fifth toe were two large granulating ulcers. On the upper part of each foot were linear scars of operations.

On the ulnar side of the right-hand was a diffuse swelling extending over the metacarpal bones, where the trochlea of the fifth metatarsal was easily felt.

On the left hand all this was absent except the scar in which was a fistula communicating with the bone from which a thin ichorous fluid oozed. The first second, and third fingers of the left hand, still intact, were thick and bent with irregular surfaces and of a light brown colour. The left knee was swollen and had a ball shape fixed in flexion. On the scalp, areas about the size of a shilling, were denuded of hair and some of them covered with favus-scutalis. The skin on the free margins of the ears was excoriated and irregular.

According to the father's story, all these changes took place gradually during the last eight years. From birth till the child was four years of age it was in perfect health and of normal appearance. Shortly after this period the hands became blue and swollen, which was soon followed by the foot and ears. As this occurred during the winter little heed was taken of it at the time, but whether the child was exposed to severe cold, as to cause frost bite, cannot be exactly determined. We learn that after this winter the ulcers on the toes commenced, and the small bones fell out of the toes, later the fingers.

Every year since this ulceration went on; in winter the parts were of a reddish blue, followed by necrosis and improvement in the warm summer season, when the bones fell out of the parts. It was three years after the invasion, or five years ago, that the dorsum of the foot began to swell; a little later the right hand, which induced the parents to leave him in hospital where they were cut open without the beneficial result expected. The swelling of the knees commenced only six months ago, after a supposed slight injury. It may be well to state that four years ago the patient was seized with a severe itching all over the body, with red blotches on he skin and favus in the hairy parts.

Examination of the nerve system was normal with the exception of a slight hyperstæhesia. Necker came to the conclusion that this was one of Raynaud's disease complicated with bone affection and articular tuberculosis.

The livid, gangrenous nature of the disease certainly points to a vascular defect, but the angiospasms, itch and vesicles point to a neurotic centre, which may be located in the vaso-motor centre of the medulla and all the phenomena induced by an irritation of that ganglia. Syphilis and hysteria have many points in common, and must always be eliminated before our diagnosis is complete, as both produce the colour and gangrene.

Tetany.

Konigstein next gave a report of his investigation of the thyroid for the morbid source of tetany. He had a typical case of spontaneous or idiopathic tetany from whom he obtained the epithelial bodies of the gland, but found the iodine colouration failed entirely when compared with the control experiment. He therefore doubts if this be the correct centre of morbidity.

Rontgen Rays and Carcinoma.

This controversial subject has yet another exponent in Freund, who acted on a woman, æt. 60. with the rays for carcinoma of the mamma. The neoplasm was three years old, in the form of a knobby swelling, about the size of a man's fist, and began to ulcerate a year ago. The skin and pectoral fascia were firmly bound up with it, and the glands of the axilla large and swollen, while the patient was in an exhausted cachectic condition. From December 27, 1905, till February 19th—about three months—twenty exposures for six minutes with a "hard" Rontgen tube were applied. The purulent discharge was converted into a serous fluid, and by the end of April disappeared altogether. Now there is nothing to be seen but a smooth cicatrix on the thoracic wall; the glandular swellings in the axilla have gone, and no appearance of metastatic nodules can be found anywhere.

Nothing now remains but the telangiecstasis common after Ray treatment.

SCOTLAND.

Graduation Ceremonial at Edinburgh University.—The summer graduation ceremony took place in the McEwan Hall on July 27th, when the degree of L.L.D. was conferred on Sir Donald Currie, Emeritus Professor Sir A. R. Simpson, Senor Antonio da Veiga Beirao, an eminent Portuguese jurist, and Baron Descamps, Professor of International law at Louvain. In presenting Professor Simpson for the degree, Sir Ludovic Grant paid a graceful tribute to his long service in the University, to his eminence in gynæcology, and to his prestige as a teacher. The occasion of the fiftieth anniversary of his graduation as a Doctor of Medicine was a most fitting time for the University to recognise the lustre he has shed on his *alma mater*. After the ordinary degrees had been given, the new graduates were addressed by Professor Annandale, who successfully avoided the usual rather hackneyed platitudes of orations of this nature, in choosing as his topic "Quackery, otherwise Humbug."

General Medical Council.—A circular has been issued by Drs. G. A. Gilson and F. W. N. Haultain, inviting the adhesion of those who are in favour of Dr. Norman Walker's candidature for the post of Direct Representative for Scotland on the General Medical Council. Although he now practises as a specialist, Dr. Walker was for a number of years in general practice in the country and hence has the knowledge borne of personal experience of the point of view of a general practitioner. Added to this is his intimate acquaintance with the educational aspects of medicine, his long experience in medical affairs through his connection with the British Medical Association, and his unrivalled business capacity—all of which seem to mark him as eminently adapted for a seat on the General Medical Council. His election would undoubtedly strengthen that body, and his very numerous friends throughout Scotland are sanguine of his success.

LETTERS TO THE EDITOR.

INSPECTION OF FOOD BILL.

To the Editor of The Medical Press and Circular.

Sir,—With regard to the Inspection of Food, Bill that has been recently introduced by the President of the Local Government Board, it seems clear enough that if it pass it will enable the Board to provide for the efficient examination of food entering the Metropolitan county. This project of law has gained the approval of the County Council Committee, which has had the question in hand. They report to the Council that Mr. Burns' Bill will, if it become law, give to London all that the Council could have expected from any Bill promoted by themselves. They, however, express the opinion that the Bill will not fulfil its purpose in London unless the Council, as the only authority having jurisdiction over the whole of the county, is made the authority in London for the administration of any regulations which may be made under the Bill. To my mind, that view expresses a condition absolutely necessary to the ultimate success of the Bill in attaining its avowed object. But surely we must have also a higher supreme authority for final administration, if necessary.

I am, Sir, yours truly,

Croydon, July 26th, 1906. Food Reformer.

THE SCOTTISH DIRECT REPRESENTATIVE ELECTION.

To the Editor of The Medical Press and Circular.

Sir,—We have been instrumental in promoting a requisition to Dr. Norman Walker inviting him to be a candidate for the post of Direct Representative for Scotland on the General Medical Council. Dr. Walker received so large a measure of support on the last occasion and has since continued to take so active and useful a part in the promotion of the improvement of medical education as well as in other matters of medical politics that we have every reason to believe that on this occasion his candidature will be successful.

The requisition has been largely signed by practitioners from all parts of Scotland, and Dr. Walker has indicated his willingness to accept it.

We shall be glad to hear from those who wish to join the General Committee.

We are, Sir, yours truly,

G. A. Gibson, 3, Drumsheugh Gardens, Edin.
F. W. N. Haultain, 12, Charlotte Square, Edin.

MOTOR CARS AND DUST.

To the Editor of The Medical Press and Circular.

Sir,—Will you allow me to remark that your note on "Motors and Influenza," on July 25th, 1906, is conceived in a deplorably anti-progressive spirit? Have you not momentarily forgotten the *role* you perform in creating that health conscience which Dr. Clouston wishes the nation to possess? The motor does not produce dust—how can india rubber grind stone into dust—it is the horse, pounding with his iron hoof, and the metal wheel of the vehicle he draws that are responsible for the condition you justly condemn. Rather enlighten your readers on the subject of the diseases traceable to the presence of the horse on the road.

I am, Sir, yours truly,

A. W. Gilchrist, M.D.

Nice, July 28th, 1906.

[Road dust is made both by attrition of macadam and by crushing up of dry mud. The soft motor wheel certainly will crush the dried mud, and it seems to us that the solid iron shod tyre beneath a heavy vehicle must grind up stones and pebbles galore. In any case

Dr. Gilchrist may be reminded that the motor is an energetic distributor of dust, which fits our argument even if his contention were right that it is not a creator of that nuisance.—ED. M.P.&C.]

MEDICAL REPORTS ON POLICE CASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The remarks in the last two issues of your valuable journal with regard to Medical reports as Police witnesses are very apt. The amount of work that a house surgeon has to do in an ordinary hospital or infirmary is quite sufficient without his being constantly applied to by this, that, and the other person for information about different patients. It ought to be no part of his regular duty to give news of patients, except in the form of a regular official report when such is needed for police or other purposes. Everybody interested in a patient thinks he has a perfect right to get hold of the house surgeon during any hour of the day or night that he is passing the hospital, to make inquiries. There ought to be a proper system for reporting patients' progress at every institution. I am constantly pointing this out to the Committee of my hospital, and I am very glad to have your remarks to support me in my contention. Please "peg away" at it. I am, Sir, yours truly,

July 26th, 1906. UNIT.

INJUDICIOUS FEEDING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Over-indulgence in either food or drink is sure to bring its own punishment later on. This may appear a "truism," but if so, is little regarded by the majority of people, who never lose an opportunity of feeding, as can be seen at almost any hour of the day by looking in at any catering establishment. There are numbers of people who imagine the more and the oftener they eat and drink the stronger they will be. The very converse is more likely the truth. In times gone by the custom existed, when introduced to another, that it was common politeness to ask him to have a drink. Nowadays, "Come and dine." I am fully assured *all should eat in proportion to the amount of mental or bodily work done*, or about to be done. Would an owner of horses, who had no work for them to do, feed them as highly as if they had a heavy day's work before them? I should imagine that the injury done by over-fasting (as in the case of professionals, who do so for gain) the lesser evil than gluttony or drunkenness. The balance between the secretory and excretory organs must be maintained if we wish to prolong our days—a suitable diet chosen and the proper quantity ingested at suitable intervals, and, as I said previously above all, in proportion to the amount of the mental or bodily work done.

Yours truly,

July 27th, 1906. ALEXANDER DUKE.

SPECIAL ARTICLES.

THE CENTRAL MIDWIVES BOARD.

AT the last meeting (Thursday, July 26th), Dr. CHAMPNEYS in the chair, the secretary read a letter from the Clerk of the Privy Council with regard to the new rules and Poor-law institutions as "approved by the Board," the Council deeming it necessary to act by the advice of the Local Government Board, who consider some such provision of midwives from their institutions needful.

"SIR,—Referring to your letter of May 9th last, I am directed by the lords of the Council to state that their lordships have given their careful consideration to the revised rules made by the Central Midwives Board and to request that you will lay before the Board the following amendments that are deemed necessary therein.

"Their lordships' attention has been called to a resolution passed by the Central Midwives Board on February 16th, 1905, 'that no Poor-law institution be approved as a training school for midwives unless the average number of deliveries reaches 75 per annum'; and also to a discussion which took place at a recent meeting of the Central Midwives Board on a memorandum which suggested that 'in future as a rule, a number of not less than sixty cases of labour annually be essential for an application to be approved from a doctor desiring to teach pupils in an infirmary or workhouse which is too small to be a recognised school'; and I am to point out that, in their lordships' opinion, resolutions which have the effect of 'regulating the course of training' come within the purview of Section 3.1.(c) of the Act, and consequently should be embodied in rules to be submitted to the Privy Council for approval.

"Their lordships are moreover advised that it would be desirable in the interests of public health, and in connection with the problem of infant mortality, that a rule should be added to Section E, making it the duty of midwives—where the supervising authority requires it—to notify within forty-eight hours to such authority every birth occurring in their practice together with the name and address of the parent.

"I am to add that with a view to ensuring sufficient consideration of the amendments to the draft rules, their lordships propose to extend the existing rules for another six months from the date of their expiry on August 12th next."

The PRESIDENT said that it was a practical detraction of the Poor-law Institutions from their hands, as they would have nothing to do with their training or examinations.

Dr. PARKER YOUNG rose to protest against the decision of the Privy Council. He was extremely sorry and surprised, and considered it retrogressive to allow the L.G.B. to supersede the C.M.B., and so make two authorities. After a delay of over two months, the rules, which it had been hoped would have been amended, were now extended over six months, and he proposed a discussion by a special committee. This was agreed to.

THE PAYMENT OF MEDICAL FEES.

In connection with a letter (read) from Mr. Ward Cousins, saying he had supported a resolution to the Privy Council in favour of amending the Act with regard to the payment of medical men called in by midwives, a letter was read from a midwife asking if any decision had been arrived at, as lately she had a case where one doctor summoned had to call in another in consultation, and the circumstances of the patient did not guarantee any fee, nor had the doctors had any.

Dr. PARKER YOUNG remarked that under the circumstances the Poor-law doctor ought to have been summoned, as the guardians had the power of making the family pay if they could or had themselves to give the fee.

The PRESIDENT added that this question of fees came up over and over again. At present, wtih regard to liability, clearly the doctor or midwife who had undertaken to deliver the woman was liable. If a midwife, then she is responsible, and the doctor called in is merely a consultant, and the nurse is responsible for obtaining his fee. People of the poorer classes were likely to, and did, seek unqualified women, fearing a L.O.S. would send for a doctor.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council, held last Thursday at the Royal College of Surgeons, Mr. Henry Morris, president, in the chair, it was decided, on the recommendation of the Board of Examiners in Dental Surgery that the period of instruction in mechanical dentistry be reduced from three to two years. The Board also expressed the opinion that it is desirable to admit a student to the first professional examination as soon as he can produce the required certificates, without necessarily completing six months' attendance at a dental school and hospital, and the council decided to alter the regulations so as to meet this

recommendation. The announcement of an interesting gift to the museum of the college was reported to the council in connection with a tree, under the shade of which both St. Luke and St. Paul, according to Dean Farrar, probably rested. The tree, which still stands in the island of Cos, in the Ægean Sea, is surrounded by a podium or raised platform, doubtless built to support the trunk of the tree after it had become hollow and weak from age. The lower branches are still well preserved, and have been shored up by pieces of antique columns, over the upper ends of which the branches have grown like caps in consequence of the pressure of their own weight. Close by the tree is a solid marble seat, which is said to be the chair of Hippocrates, the father of medicine, and it is supposed that he taught the art of healing from that seat. He was born in Cos 460 B.C. This gives a clue to the age of the celebrated plane tree, which must be considerably more than 2,000 years old. Dr. Edward Clapton, formerly physician of St. Thomas's Hospital, whose devotion to archæology is well known, sent an agent to procure some fragments of the tree. This was done, but at considerable risk, as the Sultan, who attaches great importance to its preservation, has given strict orders that no one is to touch the tree, which is, therefore, guarded day and night. The specimens which Dr. Clapton obtained have now been generously handed over to the Royal College of Surgeons, where they will be displayed in the museum. They consist of two pieces of branch, a bundle of twigs from the branches, and a small box of leaves and round button-like catkins of the plane tree. Mr. John Tweedy and Mr. Edmund Owen were elected, and Mr. Henry T. Butlin was re-elected, members of the Executive Committee of the Imperial Cancer Research Fund in the vacancies occasioned by Mr. Morris having, as president of the college, become an *ex officio* member of the committee, and by Mr. Langton having ceased to be a member of the council of the college. It was decided to send an address of congratulation to the University of Aberdeen on the occasion of the celebration of its Quartercentenary next September.

THE LOCAL GOVERNMENT BOARD FOR IRELAND AND TUBERCULOSIS.

The Local Government Board for Ireland is showing a commendable, even if somewhat tardy, interest in the struggle against tuberculosis. On at least two previous occasions it circularised the local bodies under its superintendence, and in a further circular dated June 28th, 1906, it again directed attention to the importance of the subject. Having enumerated some of the figures relating to the consumptive and tubercular death-rates, and contrasted them with the corresponding figures for England, the Board proceeds to give practical advice.

In the first instance the Board recommends the thorough instruction of those in charge of consumptive patients in all that is necessary to enable them to prevent the spread of the disease. It is advised to distribute leaflets and pamphlets bearing on the subject, and to exhibit posters in prominent and suitable places. A specimen of a pamphlet well adapted for its purpose, and a specimen poster have aleso been sent round by the Board.

Next, attention is drawn to the prevalence of general insanitary conditions, and particularly to the imperfect housing of the poorer classes.

Finally, the question of providing sanatoria is discussed. The Local Government Board points out that it is in the power of local authorities, either individually or collectively, to provide hospitals for the inhabitants of the districts, or in the alternative, to enter into an agreement with any existing hospital for the reception of sick inhabitants. The latter plan is suggested as a temporary expedient, while the former is advised as a more permanent scheme. The Board also suggests that sputum should in doubtful cases be submitted to a skilled bacteriologist.

There is no doubt that the suggestions we have just enumerated are of excellent intention, and if followed, would doubtless result in some improvement in the health of the community. We fear, however, that before any radical improvement can be effected, there must be a thorough and complete revolution in the sanitary system of the country. At present, Ireland, outside the great cities, is without sanitary control of any but the most haphazard description. The salary of the medical officer of health for an urban or rural district varies from £5 to £15 or £20 per annum. Is it possible to expect serious sanitary work under such conditions? It is within the power of the Local Government Board to refuse to sanction the appointment of a medical officer of health at any but a reasonable remuneration, but we do not remember hearing of this power being exercised. It is absurd to expect local boards to lead until the Local Government Board show the way, and we would commend to the latter the advice given by them to local bodies:—

"It is scarcely necessary to remind the Council that any efforts on their part of a half-hearted or intermittent character are not likely to be attended with satisfactory results, and that success can only be achieved by vigorous and sustained action"

The activity of the Local Government Board up to the present has shown itself by these circular letters, scattered over an interval of five years.

Let us add that all who take an interest in the struggle against tuberculosis will find much valuable material in Dr. McWeeney's Report to the Local Government Board on the International Congress on Tuberculosis held last year at Paris.

OBITUARY.

WILLIAM NOBLE SMITH, F.R.C.S.Ed.

We regret to note the death of the well-known orthopædic surgeon, Wm. Noble Smith, on June 20th, at his residence, Queen Anne Street, London. Educated medically at St. Mary's Hospital, he took the Diploma of M.R.C.S.Eng. and L.R.C.P.Lond. in 1868, and the Fellowship of the Royal College of Surgeons of Edinburgh, in 1880. He acted as house surgeon at St. Mary's and the Lock Hospital in London and at the Bristol Children's Hospital. For many years he was connected with the City Orthopædic Hospital, and at the time of his death was Senior Surgeon. He was recently elected on the Council of the Scotch Diplomates Tercentenary, and acted as one of the official delegates of that body at the recent Quartercentenary of the Royal College of Surgeons of Edinburgh. He made many contributions to the literature of orthopædic surgery. In private life he was of a most kindly, genial, and cultured disposition, and his loss will be deeply felt by a wide circle of acquaintances.

RICHARD THOMAS PARKINSON, M.D. BRUX.

We regret to record the death of Dr. Richard Thomas Parkinson, of Manchester, suddenly on the 21st ult., while visiting a patient. Death is believed to have been due to heart failure. Dr. Parkinson, who was in his 61st year, held the M.D. degree of Brussels. He was also M.R.C.P. of Edinburgh and L.R.C.P. of England. He qualified in 1873, after pursuing his studies at the Owens College.

J. H. BREACH, M.R.C.S., L.S.A.

The death of Dr. J. H. Breach, of Yattendon, took place on Wednesday, July 18, after an illness of five months' duration. For several generations the medical practice which he carried on had passed from father to son. James Henry Breach was born in 1855, and trained at King's College. He returned to Yattendon and worked with his father, succeeding to the practice in 1882. The funeral was attended by practically all the whole of the inhabitants of Yattendon, and by a large number from adjoining parishes.

R. F. COOK, M.B., M.R.C.S., L.S.A.

ONE of the oldest medical practitioners in Gateshead has been removed by the death of Dr. Robert Foreman Cook at Harrogate, on July 23. He qualified in 1863, and two years later was appointed medical officer to the Gateshead Workhouse. He held this position for thirty-two years, and for a long period was also public vaccinator in the parish. In addition to this he carried on a large general practice in the town. In October, 1897, he resigned his public appointments and retired from practice. Four or five years ago he removed to Harrogate. From 1874 to 1900 he was an officer in the 5th Volunteer Battalion Durham Light Infantry, and on his retirement held the rank of surgeon-lieutenant-colonel, with the V.D. decoration. Of a genial and kindly disposition, he was well known for his generosity to poor people requiring help, and the organised charities of the district also found in him a willing helper and active friend. The deceased gentleman leaves a widow and one son.

REVIEWS OF BOOKS.

PAVY ON CARBOHYDRATE METABOLISM (*a*).

To the physiologist who has been brought up since his earliest scientific days in the firm belief that one of the most important duties of the liver is to store the carbohydrate of the food in the form of glycogen, and to dole it out again in the form of dexture to the various tissues and organs of the body according as they indicate their need for it, the present little book, embodying most of the well-known views of Dr. Pavy, must appear somewhat heretical. But even while adhering to thisview we must in fairness admit that the views here expounded are very plausible, and are expounded and defended with wonderful clearness and exactitude. Briefly stated Dr. Pavy's theory is as follows :—(1) Dexture as such only exists in minute traces in the blood at any time in the normal individual, and it is present in the normal urine in proportion to its presence in the blood, the kidney cells not being possessed of the power of preventing its passage through them ; (2) the malton and dexture formed in the alimentary canal are built up as they traverse the intestinal epithelium into complex molecules, and are distributed to the body as constituent portions of the circulating proteid and fat. In support of this statement he points out that the proteid molecule can always be demonstrated to contain carbohydrate chains, and that fat can undoubtedly be built up out of carbohydrate. (3) The lymphocytes found in the intestinal villi probably play an important part in the building up processes. They themselves proliferate enormously during digestion, and passing into the circulation *via* the thoracic duct are accountable for the digestion lymphocytosis that normally takes place. (4) The glycogenic function of the liver is purely a reserve force, designed to temporarily stop any glucose that may have escaped "assimilation" in the villi, and all glycogen, which is retained in the liver is subsequently built up into fats or is incorporated with proteid molecules. (5) The essential primary defect in diabetes is a failure of "assimilative power" in the intestinal villi, and it is best met by a complete withdrawal of all carbohydrate from the food. In support of the above statements numerous experiments are quoted and many facts adduced, many of them quite incontestable, but yet we think that the following criticisms may be put forward, and must be answered before the conclusions can be accepted :—(1) Dr. Pavy does not seem to us to explain why it is that blood contains any glucose in the free state at all, though he apparently admits that some is invariably present. According to his view any dexture that escapes the villi should be assimilated in the liver into proteid or fat molecules. Whence then comes the free glucose of the blood, for he does not definitely accept Locivi's idea ' that the sugar which is ordinarily looked upon as being in a free form in the blood is in reality in a loosely combined state " ? (2) Should not the urine contain,normally,glucose in a state of higher concentration than it is to be found in the blood, if the kidney is incapable of stopping the glucose molecule ? Urea, uric acid and other constituents are in a much higher state of concentration than in the blood, and in diabetes the sugar also may exist in higher percentage in urine than in blood. In short, if one substance appears in higher concentration, should not others also ? and yet there is difficulty in proving that urine normally contains carbohydrate at all ! This seems to us to be opposed to the view that the renal cells cannot stop the passage of glucose, provided that glucose is admitted to exist at all in the free state in the blood. (3) No reference is made to the usually accepted statement that the blood in the hepatic vein contains more sugar than that in the portal vein in the intervals between digestion. (4) The fact that portal blood admittedly contains much glucose during the digestion of carbohydrate food is passed over too easily. If the liver function is only a reserve one, why should it be called upon after every carbohydrate meal ? (5) The statement that the fat in the lacteals of rabbits after a meal of oats must be derived from the carbohydrates of the oats, cannot be accepted until definite quantitative analyses prove that the lacteal fat is in excess of the ingested fat. The mere affirmation that it is in excess is not enough and Pavy's remark that " only from time to time are such instances as I have depicted come across " (p. 89) seems to us to be against rather than in favour of his theory.

We are much more inclined to agree with his views on the treatment of diabetes, and regard with much satisfaction his remarks on the so-called " potato treatment," while, from one of his experience, the hint regarding a return to carbohydrate food when the weight begins to fall, although the urine remains sugar free, must be regarded as most valuable (p. 104). On the other hand, his statements regarding acidosis and the stoppage of all carbohydrate food must at present, we think, be received with caution.

While offering the above brief criticisms, we must state that we have read the book with genuine pleasure, and must congratulate the author on his method of maintaining the theory with which his name has been so long associated. We recommend the work to every student of physiology and can assure him that it will afford much food for thought.

(*a*) " On Carbohydrate Metabolism." A Course of Advanced Lectures on Physiology, delivered at the University of London, May, 1905. By F. W. Pavy, M.D., F.R.S., Consulting Physician to Guy's Hospital. London : J. and A. Churchill, 1906.

THE FOOD FACTOR IN DISEASE. (*a*)

THIS is a monument of orderly research, painstaking effort, and logical arrangement. There is much that is reminiscent of a bygone pathology, but more that is quickened by modern conceptions. The work is philosophic rather than experimental. It is the product of a methodical thinker and a judicious compiler rather than the record of an original investigator. But by passing the disconnected and unexplained observations of others through the fine sieve of his own disciminating judgment, the author has succeeded in producing a work which is highly original in many of its conclusions, suggestive and stimulating in an exceptional degree, and marked throughout by a literary style, graceful and luminous, and such as is unfortunately but seldom met with in medical works. Dr. Hare states that his work is an investigation into the humoral causation, meaning, mechanism, and rational treatment, preventive and curative, of the paroxysmal neuroses (migraine, asthma, angina pectoris epilepsy, etc.), bilious attacks, gout, catarrhal and

(*a*) " The Food Factor in Disease." By Francis Hare, M.D., late Consulting Physician to the Brisbane General Hospital and Inspector General of Hospitals for Queensland. In two volumes. Vol. I. pp. xlv., 497. Vol. II., pp. viii., 535. London : Longmans, Green and Co., 1905. Price 30s. net.

other affections, high blood pressure, circulatory, renal, and other degenerations. The work is mainly deductive and not inductive. The argument is well presented and is ingenious and the facts supporting it are many, varied and substantial. Dr. Hare believes that the nitrogenous and carbonaceous materials of food differ essentially in their function and are in many respects diametrically opposed. He deals with the income and regulation of carbon to the blood, the physiological methods of decarbonisation. He seeks to show that in certain circumstances the carbon expenditure of the blood falls below its income, and that there occurs an accumulation of carbonaceous material which may be considered pathological. To this morbid blood state the term "hyperpyræmia" is applied. The greater part of these two bulky volumes is devoted to evidence which the author considers demonstrates the widely prevalent influence of this morbid condition as etiologically connected with many abnormal states, the nature of which hitherto have remained obscure. He studies in much detail the connection of hyperpyræmia with migraine, asthma, angina, epilepsy and other paroxysmal derangements, gout, uricæmia, and certain catarrhal pyrexial and hæmorrhagic conditions. It is impossible in the space at our disposal to discuss or dispute Dr. Hare's thesis, but while every page offers suggestive contentions and well-selected facts in substantiation, there is much that will not be allowed to pass unchallenged both by pathologists and cliniciens. There is much, however, in these pages of practical service. Perhaps the most generalised conclusion which will be arrived at from a consideration of the author's theory of hyperpyræmia is the need to pay greater attention to the "stoking" of the human engine. An interesting feature of the work is the well selected and excellently described series of clinical cases. Dr. Hare's volumes with their twenty-six chapters and nine hundred and fifty-eight duly numbered sections, with their careful headings, and with summary at the head of each chapter and conclusion at its end, offer us a model of orderly presentation which we would gladly see followed in some other works. Most of the work, we are given to understand, "was written in a country destitute of reference libraries," and this makes Dr. Hare's achievement even still more notable and praiseworthy, for the work teems with references, and evidently the greatest care has been taken to ensure their accuracy. The author has presented his argument with much modesty, conspicuous precision, and through all there is a scientific spirit and a literary presentation which is exceptionally fascinating; and we commend the study of these volumes to all interested in speculative medicine.

SKIN DISEASES AND INTERNAL DISORDERS. (*a*)

The four lectures contained in this volume were delivered at the New York Skin and Cancer Hospital last year and are now published by special request. The aim of the author is to impress on dermatologists the necessity of taking a broader view of the diseases of the skin than is often done by considering the relations of the skin to internal disorders. As a result of the present day specialism there is, no doubt, a tendency among dermatologists to consider the skin as an independent structure with diseases of its own, and this tendency has perhaps led to the expenditure of an undue amount of labour in the naming and classifying of these diseases. This insistence on the importance of classification may lead the student for the moment to neglect the more general principles, but it would seem to us that this neglect must be very quickly corrected by the exigencies of practice. Every physician who is worthy of the name must recognise that it is the patient, and not merely the disease as an isolated phenomenon of the patient, that he has to treat. Dr. Bulkley has pointed out many instances in which skin lesions evidently depended on general constitutional affections; but they remain merely instances, and we look in vain in his lecture for any general principles which might guide us either in diagnosis or treatment. The truth seems to be that as yet dermatology has not sufficiently advanced to enable us to formulate any such principles, except in very few instances, and for the present we must be content merely to apply to the treatment of skin diseases the obvious rules of general therapeutics. The book before us impresses this fact strongly on the reader, and consequently will be of value to many practitioners.

(*a*) "On the Relations of Diseases of the Skin to Internal Disorders with Observations on Diet, Hygiene and General Therapeutics." By L. Duncan Bulkley, M.D.Lond. and New York: Rebman and Co., 1905. 8vo., pp. xv., 175.

PUBLIC HEALTH QUESTIONS. (*a*)

Undoubtedly one of the finest exercises that the intending candidate for any examination can employ, is the answering of papers set at previous examinations. This being so, we can heartily recommend this little volume to intending Public Health candidates, inasmuch as the questions contained therein are judiciously selected and so well do they cover the prescribed course, that a student who can acquit himself credibly in answering a fair proportion of them ought to have no doubts whatever as to the advisability of "sitting" for the next examination. Having finished the course of lectures and practical work, an intending candidate can pursue no better course than spend half a crown in purchasing Dr. Jones' selection of questions and answering them.

ANATOMY AND PHYSIOLOGY FOR NURSES (*b*).

There is perhaps no more disputed question connected with the training of our nurses than that dealing with the instruction which should be given in the subjects of anatomy and physiology. That some instruction is necessary almost everyone will admit, but concerning the limits of this instruction there is still the greatest diversity of opinion. It would seem obvious that those who have to learn anatomy without the aid of dissection, and without the assistance of viewing the internal organs of the body, can only be expected to acquire a very general outline of the subject. In the book before us Dr. Lewis has set forth what he considers sufficient to enable nurses "to grasp the primary principles," but we are inclined to differ with him as to what is necessary. We believe that a simple yet comprehensive statement of those principles is much more essential than a minute enumeration of sundry details. We may illustrate our point by a few quotations. Among the "review questions" which follow each chapter, we find the following:—"How many muscles are there in the pterygomaxillary region?" It is difficult to see how such a detail is necessary for a nurse who wishes to grasp the general principles of anatomy. Again, we find the question "What is respiration?" and the nurse is expected to extract the answer from the following paragraph:—"The substances furnished to the circulation from the alimentary canal are in a condition that, with reference to the atmosphere, will admit of free combination with oxygen; this latter agent is quite necessary to prepare the tissues for the functions of assimilation and nutrition. Besides this, the venous blood is also charged with carbonated products that, when exposed to oxygen, are eliminated and passed off in the form of carbonic acid gas. To effect these several purposes and thus to maintain the motive power of the system, eliminating at the same time deleterious substances, is the function of the apparatus of respiration." To us it would appear difficult to extract the meaning of the author from this passage, and we believe very few could extract from it an answer to his question.

From what has been said, it will be obvious that we differ from our author in the solution that is to be given to the question, "How far are nurses to be

(*b*) "Anatomy and Physiology for Nurses." By Leroy Lewis, M.D. Philadelphia and London: W. B. Saunders and Co., 1905.

instructed in anatomy and physiology?" and even from his own point of view we cannot consider that the book has fulfilled its object. There is, however, much information in the book that will be of use to a nurse in the study of her profession, and the illustrations are excellent.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

THE annual volume of reports from St. Bartholomew's Hospital is always interesting, and the present one quite maintains this reputation. Mr. John Langton, F.R.C.S., contributes an interesting memoir of the late Luther Holden, whose connection with the hospital dates from the year 1832, when he entered the medical school there as a pupil of Edward Stanley. The name of Holden has been familiar to many generations of medical students through his work on "Human Osteology," which appeared in 1855. The volume contains also many very interesting papers to which the space at our disposal will not permit us to refer more particularly. We should like to draw special attention, however, to the paper by Dr. H. H. Tooth on "The Segmental Spinal Areas Considered Clinically." This paper, which is very fully illustrated by diagrams, will well repay any physician for the time spent on its study. Bound up with this volume is the General Index of the second twenty volumes of the Hospital Reports (1885-1904), compiled by W. McAdam Eccles, F.R.C.S.

AN INTRODUCTION TO VOLUMETRIC ANALYSIS. (b)

A STUDENT beginning volumetric analysis is as likely as not very slow in grasping the fundamental principles of this branch of analysis, and the teacher capable of explaining the same must perforce be gifted with great powers of lucid expression. Again, the text-books assume, often quite erroneously, that the lectures and demonstrations are sufficient to make the subject quite clear to the student, and should the latter seek the aid of the average text-book on practical chemistry, his knowledge of the principles of volumetric analysis will not be augmented to any appreciable extent. The small volume by Drs. Walker and Mott will, we think, be a boon to both student and teacher, the instructions for the experiments and the explanations of the processes being ample to both help the student to understand and to prevent the mechanical performance of the experiments, which is the *dernier ressort* of the unfortunate student, who either cannot reason the matter out for himself, or is under the tuition of one whose verbiage is not suited to the difficult task of teaching volumetric analysis.

BIOGRAPHIC CLINICS (c).

IN the volume before us Dr. Gould adds two more to the clinical biographies which he has recounted in the previous volumes. We have here a study of the ill-health of John Addington Symonds and of Taine; in each case the explanation of the symptoms is found in uncorrected errors of refraction. Symonds died at the age of fifty-three from, we believe, pulmonary tuberculosis, which had begun more than twenty-five years before, and Dr. Gould has no difficulty in showing that many of the symptoms of ill-health which were present during this long period were not those of the pulmonary disease. As a matter of historical biography it is of great interest to find an explanation for the symptoms exhibited during their lifetime by the illustrious dead, but as a contribution to the practice of medicine it is of doubtful value. Such explanations must be at best hypothetical and must for ever remain so and consequently bring no conviction to the sceptical. Dr. Gould, however, does not entirely depend on such hypothetical proof of his contention as to the evil effects of eyestrain, for in the book before us we have many cases quoted where the clinical history was completed during the lifetime of the patient. Two papers of great interest, one by Mr. Simon Snell and the other by Mr. Ernest Pronger, are reprinted in this volume, and both of them contain the histories of many cases which prove, as far as proof is possible, the great influence of slight errors of refraction on the nervous system. We must frankly confess that Dr. Gould has convinced us by this book of the truth of his thesis and we trust that it will be widely read by medical men, believing fully that it will carry conviction to them also.

HOWELL'S PHYSIOLOGY. (a)

THE author of this text-book has endeavoured to "keep in mind two guiding principles: first, the importance of simplicity and lucidity in the presentation of facts and theories, and, second, the need of a judicious limitation of the material selected." He has certainly succeeded in producing a manual of physiology conspicuous in its clearness and as attractive as it is comprehensive. The book is divided into five main sections, and there is an appendix dealing with the chemistry of the proteids and the physics of osmosis. That part treating of the central nervous system and the special senses is very full, the physiology of sleep and fatigue having more than usual consideration. The special senses are divided into two groups—(1) the external or exterior, and (2) the internal or interior. Of the olfactory sensations, the classification by Zwaardemaker is adopted, no less than nine classes of pure odours being described. A brief reference only is made to the precipitation test for blood, but the reader is directed by a footnote to the recent work of Nuttall. The opsonic power of blood is not included in the description of immunity and the means provided by the body for combating infection from without. In the section on digestion and absorption the now well-known work of Chittenden in connection with physiological economy in diet is fully described. A few little inconsistencies, chiefly of etymology, are to be found scattered throughout the book; *e.g.*, if the term "mydriatic" be allowed, why is "miosis" retained? The student is not overburdened with references, but these are nearly always added after the introduction of recent matter or conflicting theories, the work of the principal European and American physiologists being fully drawn upon. The book is well illustrated with several coloured plates and numerous woodcuts. On the whole we can thoroughly recommend it as a reliable text-book for students or practitioners.

LABORATORY METHODS. (b)

SOME excuse is needed for the appearance of another volume devoted to laboratory methods in clinical pathology, and one consequently takes up the book under review with a certain doubt of the necessity of its existence. A very short perusal, however, is sufficient to dissipate any such prejudice, and to convince one that the book is, as might be expected from the reputation of the authors, one of great intrinsic merit. In fact, we know no book on the subject which contains so much information in so small compass. The directions given are clear and concise, and the authors have used discretion in omitting those methods that may be regarded as obsolete. It is a question whether, in a book of this sort, it is possible to treat

(b) "Methods of Morbid Histology and Clinical Pathology." By J. Walker Hall, M.D., Lecturer in Pathology, Victoria University of Manchester; and G. Herschelmer, M.D., Prosector to the Städtisches Krankenhaus, Wiesbaden. Edinburgh; Williams, Green and Sons, 1905. Pp. xvi., 290.

bacterioscopic methods with profit, but a perusal of the thirty-three pages here devoted to the subject almost persuades us that it can be done. The chapter on Blood is good, and the most recent methods of fixing and staining are detailed. The writing is not always as careful as it might be, and some unusual words are employed. We see no reason, for example, to invent such a term as "Sectioning" to stand as title to a chapter. Some of the author's suggestions in the working of various processes had better be neglected, as when they advise to "warm the surface (of a frozen object) by rubbing it with the fingers" before attempting to cut it. These, however, are minor faults, and we have no doubt the book will speedily take its place as one of the most used in clinical laboratories.

A SYSTEM OF MEDICINE BY MANY WRITERS. (a)

We welcome with great pleasure the first instalment of a new edition of this standard work. "Though," as Professor Allbutt in his preface rightly says:—"the present work cannot be said to be out of date," it has been thought desirable to commence the publication of a new edition. The Editors have therefore arranged for the publication of a volume annually, which will re-place in turn the corresponding volume of the old edition.

The present volume consists of two parts or divisions. The first of these deals with subjects introductory to medicine, and the second with some of the acute infections. The changes which have been made amount to far more than mere revision, as a great part of the work has been re-written. The first article, on the history of medicine, is a new contribution by Professor Allbutt and Dr. Payne, and in some measure replaces the original introduction which was written by Professor Allbutt, and which has now been omitted. The article on Medical Statistics has been entirely re-written by Dr. Tatham, and constitutes a very important contribution to the literature of this subject. A new article on the medical geography of Great Britain has been contributed by Dr. Clemow. Sir Hermann and Dr. Parkes Weber contribute an article on Old Age, while Dr. Hutchison contributes a section on the physiological principles of dietetics. New articles have been added on Exercise in the Treatment of Disease, and on X-rays. Dr. F. W. Andrews has re-written the article on the General Pathology of New Growths, while additions have been made to the article on Fever by Dr. Pembrey and Dr. Hale White. Other additions of importance have also been made to many of the remaining articles.

It is neither possible nor necessary to subject an established work of the class of Professor Allbutt's System of Medicine to criticism—its length forbids, and its character excuses the absence of such treatment. It is sufficient to say that the new volume more than maintains the reputation of its predecessors in its completeness, literary characteristics, and erudition. If we may select an article from so many of high standard as being specially worthy of praise, it is that on "Inflammation," by Dr. J. G. Adami. This noteworthy contribution is so complete in itself, and treats of its subject with such minutiæ, that it may be considered rather as a monograph, which should stand alone, than as a contribution to a text-book.

The Editors expect that Volume II. will appear towards the end of the present year. It will consist of two parts, The first of these will contain the late Professor Kanthack's contribution on the General Pathology of Infection and Immunity, revised and in parts re-written by Professor Ritchie of Oxford. The second part will be devoted to Tropical Diseases. In conclusion, we may congratulate Professor Allbutt on his co-Editor, Dr. H. D. Rolleston, whose name appears for the first time on the title-page.

Vol. I. Pp. xvi. and 1209. London: Macmillan and Co., Ltd. 1906

CHAVASSE'S ADVICE TO A MOTHER. (a)

This justly popular volume, well remembered by many in nursery days, has been the succour and solace of many a distressed mother and has doubtless soothed and accomplished much in the sorrows of infancy and assuaged the aches and pains of helpless childhood. The anxieties of motherhood are very great and the difficulties of early days are not easy to surmount. "Chavasse's Advice," has for several generations been an inseparable companion of mothers. But while the mystery and majesty of motherhood remain ever unchanged, the progress of medicine and the advance of sanitary science makes it necessary to revise and extend even such a tried and trusted counsellor as this little domestic handbook.

Dr. Lister is to be congratulated on the wise discrimination and conscientious care with which he has accomplished the rejuvenescence of this old favourite. The old-fashioned but effectual and undoubtedly impressive catechetical arrangement is retained, and the same familiar fatherly dogmatic directions are given, but withal there is an up-to-dateness and modernity which is refreshing. We are glad to find that Dr. Lister does not hesitate to condemn old-time dangerous procedures born of ignorance and superstition. This is particularly noticeable in the sections dealing with the administration of alcohol to nursing mothers and children.

In some quarters it is fashionable to ridicule such an eminently mother's book as this. It is one, however, which, rightly viewed, instead of replacing the family doctor, should do much to indicate his necessity and assist in the very purpose for which he exists.

We unhesitatingly commend this homely volume. It is a work which many a newly qualified practitioner, and, indeed, some rusty and old-fashioned family physicians, might well study with advantage both to their professional reputations and the health and happiness of their little patients.

PUERPERAL FEVER. (b)

When Dr. Cullingworth gave his address on "Oliver Wendell Holmes and the Contagiousness of Puerperal Fever" to the Bath and Bristol Branch of the British Medical Association last October, we congratulated him on his choice of a subject. We are glad, therefore, to see this reprint of the lecture enforced by appendices on related subjects. There is no more interesting chapter in the history of medicine than that which relates to the progress of our knowledge of puerperal fever, and in this chapter two names stand out above all others—Holmes and Semmelweis. Not even to Pasteur and Lister do we owe so much in this particular respect. It is true that Holmes had predecessors, among whom the chief are White, of Manchester and Gordon, of Aberdeen, but Holmes was the first to marshal his facts in logical order, and to move his battalions into action as in a great warfare. Be it said, too, that although his essay was published in April, 1843, it could not be improved to-day by the addition or subtraction of a line—leaving out of account, of course, arguments based on bacteriological study, which has sprung into existence since that time. The essay is, indeed, one of the classics of medicine, and Dr. Cullingworth does not exaggerate when he compares its noble and fervid eloquence to that of the Hebrew prophets. Speaking of it, the author himself once said, "for doing which humble office I desire to be thankful that I have lived, though nothing else good should ever come of my life." Much good has come of Holmes's long, laborious, and distinguished, life, but nothing greater than his "battle for the poor poisoned women."

MEDICAL NEWS IN BRIEF.

Presentation to Dr. Coleman.

ON July 24th, a deputation of the leaders of the medical profession in Ireland presented Dr. Coleman with a resolution signed by 1,300 medical practitioners in reference to recent legal proceedings. The gentlemen who presented the resolution were the Presidents of the Royal Colleges of Physicians and Surgeons; Sir Arthur Chance, Sir Christopher Nixon, Bart., Sir Francis Cruise, Sir Wm. Thomson, Sir Arthur Macan, Dr. J. Magee Finny. The President of the College of Physicians (Sir W. Smyly) occupied the chair, and in addressing Dr. Coleman, said for a long time his brethren of the medical profession had felt with the most earnest solicitude the course of events in which he (Dr. Coleman) had been so deeply concerned. And although those of the profession who had known him personally never for a moment had a doubt as to his innocence of the charges which were brought against him, yet they could not but feel that it was a matter for thankfulness and for congratulation that he was able to refute those charges and that the jury and the judge had declared that he had passed through that terrible ordeal without a blemish on his professional or private character. Under these circumstances, it was not only proper, but was most fitting that they, his medical brethren, should have an opportunity of expressing to him their sentiments. As to their authority for so doing, he might explain that they, as Presidents or vice-presidents of the Royal Colleges of Medicine and Surgery, had been deputed by a large and representative meeting of the medical profession, assembled in Dublin, to convey to him a resolution signed by upwards of 1,300 of his brother practitioners throughout the country. The following was the resolution:—"That we, the professional brethren of Dr. James Byrne Coleman, congratulate him on the successful manner in which he has recently refuted the unfounded charges brought against him and express our sympathy with him in the trouble through which he has passed without blemish on his character or honour." Mr. H. R. Swanzy, as President of the Royal College of Surgeons and all that it represented desired to associate himself with the words which had been spoken by the President of the College of Physicians. He could assure Dr. Coleman that from the moment they first learned of the nature of the charges made against him they felt that he could be nothing but innocent of them; but their hearts went out to him in sympathy. This was no light-hearted sympathy, nor was it a restricted and unconsidered one; but it was not at all difficult to see the grounds upon which they founded their opinion. For many years, almost, they might say, since Dr. Coleman came to manhood, he had been under their observation as student, as house surgeon, and as physician in a great public hospital, as a practitioner of medicine in their midst. They had thus ample opportunities of learning his character. They knew the kindness of heart, they knew him as a skilled and gentle and well-beloved physician, full of sympathy for the sufferer, and unfailing in courtesy to him. The album containing the resolution, with 1,300 signatures, was then presented.—Dr. Coleman, in replying, said—Gentlemen, I thank you from my heart for the very great honour which you, the leaders of the medical profession in Ireland, have conferred on me here to-day, in conveying the resolution which has been read, and I thank the President of the College of Physicians and the President of the College of Surgeons for the all too kind words in which they have referred to me. I am grateful beyond measure to the signatories of the resolution for the kind spirit which prompted them to express their sympathy with me in my great trouble. Such a manifestation of confidence and of sympathy is of priceless value to me, and it gives me new courage to take up again the threads of my broken life. Gentlemen, I shall never forget your great kindness to me; and all I can do is to give expression in this very inadequate way to my feelings of gratitude to you, and my sincere thanks to you. The proceedings then terminated.

"Bile Beans" Appeal.

THE appeal of the "Bile Beans" Company against the ruling of the lower court, which had refused to protect their trade-mark, was dismissed in the Court of Sessions on July 22nd. In delivering judgment the Lord Justice-Clerk said bile beans were said to be made of Australian vegetable substances discovered by a Charles Forde. The place of the discovery, the mode of it, and the instrument of it were all deliberate inventions, without any foundation in fact. The story was that Charles Forde, described as a skilled scientist, had noted the fact that the natives of Australia were free from bodily ailments, and that after research and investigation he had ascertained that that immunity was obtained by the vegetable substances. All that, in every particular, was false. There was never such a person as Charles Forde, and there was no eminent scientist engaged in such research in Australia. The truth was that the complainers had formed a scheme to palm off upon the public a medicine obtained from America, and they created a demand by flooding the country with advertisements, placards, pamphlets, and imaginary pictures. The complainers desired protection for the name "Bile Beans," but being themselves engaged in perpetrating a fraud upon the public, they were not entitled to any such protection.

The Criminal Appeal Bill.

THE following resolution has been passed by the Criminal Law and Prison Reform Department of the Humanitarian League, and copies have been forwarded to Sir Henry Campbell-Bannerman and Mr. Herbert Gladstone:—"This Committee of the Humanitarian League would earnestly impress upon His Majesty's Government the importance of passing the Criminal Appeal Bill during the present session of Parliament, as we believe that the Bill would receive the support of an overwhelming majority of the House of Commons. We regret to see no improvement in the Criminal Department of the Home Office, whose defects as an appellate tribunal are now generally recognised. On the contrary the number of miscarriages of justice corrected during the present year has so far been unusually small; and we submit that the creation of a properly-constituted Court to re-try criminal cases ought to be regarded as a matter of the utmost urgency."

London Temperance Hospital.

A PARTICULARLY pleasing incident took place last week at the meeting of the Board of Management of the London Temperance Hospital, when the matron made a presentation to the Board on behalf of the nurses. The Board are under the necessity of erecting a new building for their Out-patient and Casualty Departments, and have found some difficulty in raising the £10,000 involved. The present nurses, together with a few past nurses, have among themselves collected £130 towards this object, and the Matron found a purse containing this sum and a card with the following inscription upon her table, on the morning following her return from her summer vacation: "To Matron, the enclosed £130 for the new Out-patient Department, from the present and a few past nurses of the London Temperance Hospital, in token of their affection for their training school." The members of

the Board were very much gratified and impressed by this kindly token of sympathy and interest by the nursing staff, and adopted a special resolution to record the event on the minutes of proceedings.

PASS LISTS.

Royal Colleges of Physicians and of Surgeons, England.

The following are the names of the fifteen candidates who have been recommended by the Examiners for the Diploma in Public Health, viz. :—John Howard Cumpston (Melb. & Univ. Coll.), Lancelot Hugh Hale (St. George's), John Molyneux Hamill (Camb. & St. Barth.'s), Jonas William Leake (Charing Cross & R.A.M.C.), Hugh Allan Macewen (Glasgow), Sidney Herbert Nathan (Camb. & St. Geo.'s), Lionel Edmund Parker (St. George's & R.A.M.C.), Thomas Phare Puddicombe (St. Thomas's & King's Coll.), Daniel Macpherson Taylor (Glasgow & Leeds), John Francis Taylor (London & Univ. Coll.), William John Thomas (Middx. & Cardiff), Jack Mowbray Thomson (Sydney & Univ. Coll.), Henry Beckles Walton (St. Mary's, Netley, and Univ. Coll.), Hugh George Webb (St. Mary's, R.A.M.C., and London), Charles Savill Willis (Sydney & Univ. Coll.)

The Court also recommended that the Diploma of Member be issued to the 103 Candidates whose names are included in the following list, viz. :—Charles Amarasuriya, Lorimer John Austin, George Frederick Selborne Bailey, George Charles Barnes, Richard Dunlop Barron, Winfred Kelsey Beaman, Norman Bennett-Powell, Harold Bevis, Lionel Hethorn Booth, Walter Henry Skardon Burney, John Butterworth, Norman Huthnance Bye, John Graham Castellain, Fredk. Hercy Montagu Chapman, Betram Walter Cherrett, Thomas Alexander Clarke, Bevil Molesworth Collard, David Horace Collingham, Harold Percy Crampton, Henry Neville Crowe, Samuel Wilfrid Daw, Joseph Taaffe de Coteau, William Frederic Denning, Gurth Eager, Kenneth Edward Eckenstein, Rupert Farrant, William Stephen Fenwick, Alexander Fleming, Robert Long Gamlen, Nadir Hormazshaw Gandhi, Henry John Gauvain, Ernest William Giesen, Vivian Bartley Green-Armytage, Cyril Verity Griffiths, Edward William Dacre Hardy, George Atkin Hayman, John William Heekes, Reginald Beaumont Heygate, Carl Cornelius Hickey, Richard Athelstane Parker Hill, Richard Chambers Hill, Joseph Henry Howitt, Godfrey Martin Huggins, Cyril Bertram Hutchison, Claude Johnson, Alfred Lancelot Jones, Harold Emlyn Jones, James Reginald Kemp, Charles Matheson Kennedy, James Armstrong Kilpatrick, Alexander Kinder, William Wilfrid King, Basil Thorn Lang, Crichton Stirling Lee, David Thomas Lewis, Percy Collins Litchfield, Patrick Francis McEvedy, Charles McMane, Herbert Cecil Malleson, William Burton Marshall, Vernon Lickfold Matthews, Edward Meredyth Middleton, William Henry Miller, William Arnold Milner, William Cecil Morrison, Albert Clifford Morson, Herbert William Moxon, Frederick William Murray, Charles Melton Ockwell, Hubert Arnold Pallant, John Paulley, Henry Austin Philpot, Constant Wells Ponder, Joseph Marshall Postlethwaite, Edgar Nelson Ramsbottom, Allan Coats Rankin, Hubert George Rickman, Charles Sangster Rivington, Richard Pugh Rowlands, Harold Kenneth Salisbury, Gerald Claude Scott, George Elliott Seldon, Edward Fretson Skinner, Alexander Buchanan Smillie, Walter Heaton Smith, George French Stebbing, William Hugh Raymond Streatfeild, Pheroze Kharsedji Taraporwala, Reginald Thane Taylor, Edmund James Fairfield Thomas, Robert Evans Thomas, Arthur William Dunville Thomson, Frederick Boileau Treves, Sydney Arthur Tucker, Stuart William Jackson Twigg, Harold Arthur Robert Edmund Unwin, Rubens Wade, Kenneth Macfarlane Walker, John Black Ferguson Wilson, Alfred William George Woodforde, John Charles Wootton, Ernest Wragg, Everard Lister Wright.

University of Aberdeen.

At the graduation ceremony on July 25th, the following degrees were conferred :—

Degree of Doctor of Medicine (*M.D.*).—*Hugh Stewart Brander, M.A, M.B., Ch.B. ; *Alexander Flett, M.B., Ch.B. ; James Gilchrist, M.A., M.B., Ch.B. ; Alexander Gregor, M.B., C.M. ; David Mitchell Macdonald, M.B., Ch.B. ; Wyndham Anstruther Milligan, M.A., M.B., C.M. ; Alex. Murchison, M.B., C.M. ; Maurice Waugh Renton, M.B., C.M. ; Harold Traill Skae, M.B., Ch.B. ; †Wm. Clark Souter, M.B., Ch.B.

Degree of Master of Surgery (*Ch.M.*).—Isaac Frederick Bernhardi de Villiers, M.B., Ch.B.

Degrees of Bachelor of Medicine (*M.B.*) *and Master in Surgery* (*C.M.*).—Lawrence Cartwright, Thomas Robert Travell.

Degrees of Bachelor of Medicine (*M.B.*) *and Bachelor of Surgery* (*Ch.B.*)—‡Roderick McKenzie Gunn, (with Second Class Honours). Ordinary Degree—Henry Begg, William Begg, Francis James Browne, Robert Chalmers, James M'Killican Clark, George Cooper, James George Copland, M.A., William Dalgliesh, Hubert Karl W. H. Dornhorst, Robert James Duthie, Theodore Grant Gray, Alfred Petrie Hall, George Frederick John Hendry, James Laing, M.A., James Meajns Macdonald, James Ross Mackenzie, Robert William MacPherson, Douglas John Marr, Alexander Noble, Alexander Paterson, M.A., Patrick Manson Rennie, Albert Nathaniel Ewing Rodgers, George Ernest Ross, M.A., James Arthur Scharenguivel, Henry Smit, Charlotte Augusta F. S. Sturm, Alexander Frank Wallace.

Note.—James Elmsly Mitchell has passed all the examinations, but will not graduate until he has attained the necessary age.

*Commendation for Thesis.

†Honours for Thesis.

‡Passed Final Examination with distinction.

The Lyon Prize (awarded to the most distinguished graduate in Medicine of the year ; and the *John Murray Medal and Scholarship* were won by William Alexande Hogg M'Kerrow, M.B., Ch.B., of Workington.

The Alexander Anderson Scholarship was awarded to James M'Intosh, M.B., Ch.B., of Aberdeen.

The Diploma in Public Health was granted to Charles Butchart Gerrard, M.B., Ch.B. Aber. of Aberdeen. Presentation to Dr. Steede.

Indian Medical Service.

The following were the successful candidates at the examination for admission to the Indian Medical Service, held on July 24 and four following days:—J. Taylor, M.B., A. D. Stewart, M.B., C. H. Cross, R. A. Chambers, M.B., R. H. Bott, F.R.C.S., N. N. G. C. McVean, M.B., J. Morison, M.B., S. G. S. Haughton, M.B., F. W. Cragg, M.B., N. S. Simpson, S. Singh, R. F. Hebbert, M.B., J. F. James, M.B., J. Smalley, M.B., A. S. Leslie, M.B., C. M. Roberts, M.B., A. P. G. Lorimer, M.B., W. M. Thomson, M.B., H. B. Scott, F. C. Fraser, M.D. Forty-seven candidates, thirty-two of whom had University qualifications and five Fellowships of the Colleges of Surgeons, competed for the twenty vacancies. A few extra vacancies will probably be given in the course of the next few days.

The Royal Colleges of Physicians and Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow.

At the July sittings, held in Glasgow, the following candidates passed the final Examination and were admitted licentiates of the three co-operating authorities :—James Henry Allan, Liverpool ; Owen Thomas Jones, Bangor, North Wales ; Robert John Jones, Penygroes, North Wales ; James Alfred Ashurst, Govan ; Gavin Watson Hill, Hamilton ; John M'Arthur, Newmains ; Ratilal Rangildas Bakshi, India ; Adam Hill, Ballymoney, co. Antrim ; Edward John Stubbs, Stratford, Ontario ; Ernest Clinton Chandler, Montreal ; Lakshmipati, India ; Lawrence Albquerque, India ; Mahomed Samiullah, India ; Patrick John Alexander Curtin, India ; Andrew Baxter, Essex ; Jalibai Bomanji Engineer, Hyderabad ; Ronald Archibald Taylor, London.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Puerperal Sepsis.—Jackson (*American Journ. of Obstet.*, July, 1906) says why an obstetrical case should not be conducted with the same regard for asepsis as a surgical case is a mystery, but oftentimes they are not. The writer, therefore, insists on a strict prophylaxis, consisting of surgical cleanliness on the part of the doctor and everything that is to come into contact with the patient. Make the whole procedure a surgical one, and impress the patient and the family of its import. Dispense with antepartum douching unless in the face of necessity. Wear rubber gloves; make no vaginal examinations after the birth of the child unless there is an absolute reason. Suture any perineal wound, leaving wounds of cervix alone unless compelled by hæmorrhage. Make as few vaginal examinations as possible, careful abdominal palpation is better, and there is no danger of infecting the patient. Do not allow the child to be forced between a loaded bladder and rectum. If the lochia is foul, profuse and frothy, examine the cavity of the uterus with your finger and have a bacteriological examination of the lochia if it can be done. The wall will usually be rough, and the cavity filled with blood clots, secundines, or some *débris* that should be removed. Preferably this *débris* should be removed by the finger, but if the curette is used great care should be exercised not to destroy the granulation zone; finish then with a saline douche given gently. If the symptoms are those of true sepsis, the above-mentioned treatment is not to be used. Above all things do not curette; it is no less than criminal. Not only is the incomplete protective zone destroyed, but the infection is spread. Do not weaken the patient by purges, but dilute the poisons with normal salt solution per rectum, subcutaneously or intravenously. As local treatment the author recommends "the alcohol method," which is carried out as follows: Lift the patient on to a table in a good light; carefully clean the vulva and vagina by soap, water, alcohol, and a 2 per cent. eysol solution; mop and dry vagina, and insert a Sims' speculum. The cervix is seized in a vulsellum, and cervical canal is cleaned by means of gauze. The uterine cavity may be irrigated with a normal saline solution, or wiped with pure carbolic in case of a membrane being present, and then dried with gauze. A double current drainage tube is then introduced to the fundus, and a solution of 50 per cent. alcohol is thrown through the tube with a glass syringe. The vagina is now packed lightly with gauze, and the nurse is directed to inject from two to four ounces of the 70 per cent. alcohol through the tube every few hours. This will not only cleanse the cavity, but will act as a powerful non-toxic antiseptic. F.

Pelvic Pain.—Bonney (*Annals of Gynæcol.*, March, 1906) says the three most common causes of pelvic pain are backward displacements, prolapse, and disease of the appendages. The pain of retroversion and retroflexion is referred to the sacrum, and there is often further pain radiating outwards across the front of the lower abdomen and parallel with Poupart's ligament. This pain is modified by dorsal decubitus, but not entirely relieved. The pain due to prolapse is primarily referred downwards through the vagina, and is of a "bearing down" character. The pain is also referred to the sacrum and lower abdomen. It is instantly relieved by recumbency. The pain due to chronic disease of an appendage is felt in the lower abdomen, radiating outwards parallel with Poupart's ligament, and is conspicuously not modified by recumbency. Indeed, it is often worse at night. In examining women for the cause of alleged abdominal pain, it is very important to investigate the condition of the kidney. F.

Serum Treatment of Puerperal Fever. — Peham (*Archiv. f. Gynakol.*) records and analyses cases of puerperal fever treated with Poltauf's serum in Vienna. These experiments prove that puerperal infections caused by streptococci are influenced by the administration of this serum, however severe the infection may be. The influence of the serum depends upon its administration at the earliest possible moment, and upon the use of relatively large doses. In disease of long duration and in the presence of serious organic lesions the serum is powerless. It would seem, also, that it is unable to prevent the advance of localised suppuration processes such as metastatic abscesses. The serum does not produce any bad effects even in those cases in which the disease is due to infection by organisms other than streptococci. F.

Bacteriological Investigations of Operation Wounds: Concerning their Infection, with a New Proposal for its Prevention.—Döderlein, Tübingen, communicated during the 35th Surgical Congress (*Zentralbl. f. Gyn.* No. 27, 1906) the results of bacteriological examinations of the field of operation during 100 laparotomies. In spite of the most thorough asepsis, combined with the use of rubber gloves, face masks, Küstner's rubber towel for covering over the field of operation, etc., the abdominal cavity as well as the abdominal wound was found to be septic at the end of operation in every case. Döderlein believes therefore, in conjunction with Brunner, Schenk and Lichtenstern, that the skin around the area of operation is the principal source of infection in operation wounds. For laparotomies, therefore, the skin of the abdominal wall must be considered, and in order to prevent it giving out its bacteria, he recommends the following treatment: After the usual preparation of the patient, thorough baths, shaving, etc., the skin around the field of operation and the surrounding parts is rubbed over immediately before the operation with formalin-benzine or iodine-benzine (Heussner), and then painted with pure tincture of iodine. Over the latter a very carefully sterilised rubber solution is spread. By this means a rubber membrane firmly attached to the skin is produced. The rubber solution on the skin dries after a few minutes owing to the evaporation of the benzine, and its adherent properties are increased by sprinkling it with sterilised chalk. We have now a thin, smooth, sterile rubber membrane firmly attached to the skin, which all through the operation absolutely prevents the skin from giving up its bacteria. Numerous cultures demonstrated by the speaker showed the absolute freedom from infection in operations performed with this protection. He said in conclusion that by thus preventing this last source of infection, Lister's ideal of absolute cleanliness is reached. G.

Deprivation of Salt in Cases of Hydrops Gravidkatis is discussed by Cramer (*Monatssch. f. Geb. u. Gyn.* Bd. 23, Hft. 4). He sums up his paper as follows: The œdema is caused by a toxic disturbance of the eliminating powers, and its disappearance may be brought about by not giving salt in the food. The frequently observed œdema of the lower extremities occurring during pregnancy is not due to obstruction but to gravity, and can only appear when the hydrops has reached a certain limit. A direct connection between the hydrops graviditatis and the kidney of pregnancy of Leyden is not proved, since albuminuria is observed

when the œdema is disappearing or has not been present. It is necessary to replace the usual term, "the kidney of pregnancy" with "the albuminuria of pregnancy," and the conception of the kidney of pregnancy must be increased so as to include the disturbances of the kidney function which occur without causing albuminuria. The clinical definition of eclampsia requires alteration in the same way, since we must recognise eclampsia without convulsions. We also observe eclampsia without œdema. At the same time the combination of hydrops, albuminuria and eclampsia is a common one. The author cannot say for certain that the deprivation of salt has any ill effect on the development of the ovum. G.

The Prophylaxis and Radical Cure of Post-Operative Ventral Hernia.—Schutze (*Monatssch f. Geb. u. Gyn.*- Bd. 23. Hft. 4) is driven to the opinion that the incision in the middle line in the linea alba protects the tissue of the abdominal wall to the greatest extent. It requires the shortest time and promises just as firm a scar as the vertical incision outside the middle line or the transverse incision. The wound in the fascia unites so thoroughly when the suturing is properly done that the fascia recovers its normal firmness. The best suture material is antiseptic silk (Turner's). The condition of the abdominal walls whether they are firm or lax, fat or thin, has no influence on the later resisting power of the scar. Pregnancies and deliveries cannot produce separation of a really well consolidated fascia-scar. The methods of Gottschalk, Winter and Karewski are the best for the radical cure of post-operative ventral hernia. G.

The Treatment of the Placental Stage is considered by Strassmann (*Zeitsch. f. Geb. u. Gyn.*, Bd. lvii, Hft. 2). He says when a placenta is still attached to the uterus gentle pressure on the fundus uteri fills the umbilical vein strongly with blood, so that the hand holding the cord feels a fluctuation wave in the vein. After separation of the placenta one does not get this sign any longer. The placenta should not be expressed before 30 minutes post partum except all the signs of separation are present. If the latter are not present one must wait, and the attempt to express must not be repeated oftener than every half hour. After artificial delivery the hæmorrhage from the different small tears is no indication for immediate delivery of the placenta. In practice the placental stage must not be considered as completed when the placenta is born. The physician must watch the uterus for at least half an hour, and then express any blood-clots in the uterus or in the vagina. After manual removal of the placenta or portions of it, the uterus and vagina need not be washed out at all, or one may use sterile saline or weak lysoform solution. In any case antiseptics and alcohol should be used with care on account of the danger of absorption. G.

X-Ray Burns.—At the 337th regular meeting of the New York Dermatological Society the subject of X-ray burns was taken up, and Dr. Henry G. Piffard, Emeritus Professor of Dermatology in New York University, said, according to the *Journal of Cutaneous Diseases*, "that he had obtained the most benefit in treating these conditions from antiphlogistine, chloride of zinc, high frequency current and ultra violet rays."

Spontaneous Rupture of Hydrocephalus.—A case is recorded by Veninger (*Wien. Med. Woch.*, February) in which rupture of a hydrocephalic head took place. The child appeared normal at birth with the exception of a slight degree of spina bifida, at the lower end of the sacrum, a small sinus led into this spinal protrusion, and from the sinus a little cerebro-spinal fluid escaped for two or three days, then ceased, and the opening closed. At once the head began to enlarge, and soon became to a marked degree hydrocephalic. While the infant was being gently lifted, the head suddenly burst, some three litres of clear fluid coming away. The head resembled a large flaccid bag. It is interesting to note that the infant rapidly recovered from the shock of this accident, and seemed none the worse for some seven days; on the eighth day profuse diarrhœa set in and the child died. G.

Rupture of the Uterus.—Rowstron (*Brit. Med. Journ.*, July 7th, 1906), describes a case of this complication which occurred in his practice. The patient was a thin, ill-nourished woman, pregnant for the third time, æt. 28. When first seen, the pains occurred every ten minutes, moderate in type. The membranes were ruptured, and the os not quite fully dilated. The child presented as a first breech. When seen again an hour and a quarter later the pains were very strong, but the breech had made no advance. Chloroform anæsthesia was induced and the legs brought down and half an hour later the body was delivered. Friction was then applied to the legs and body but proved ineffectual, the pains meanwhile passing off and stopping altogether at the end of another half-hour. The pulse was then 100. Abdominal palpation revealed part of a fœtal head to the left and below the umbilicus, and as the sutures were felt with the greatest ease through the abdominal wall, the uterus was judged to be ruptured. The question then presented as to whether delivery should be ejected via the abdomen or vagina. Since the larger portion of the head had not yet passed through the rupture the latter route was chosen. Forceps were applied to the after coming head and the child—with hydrocephaly and spina-bifida, was delivered. An abdominal section was rapidly performed and the rent closed in two layers. It was 3½ in. in length and lay in the left posteriolateral region involving the fornix and whole length of cervix. The patient's condition was such that she succumbed four hours after the operation. There had been a quantity of clot and fresh blood in the peritoneal cavity. H.

An Anencephalic Monster.—Edwards, Penzance, June 30th, 1906 (*Brit. Med. Journ.*)—A primipara, æt. 19, was delivered of an anencephalic fœtus which survived birth for forty-eight hours. Its weight was 7 lbs., and length 20 in., and in appearance was well nourished. The cranial bones could be felt ending abruptly. The vertex was covered with hair, save in the middle line, where an irregular mass of brain matter protruded through. When slight pressure was made on this mass, rhythmical movements were set up, of the head, body, and limbs. The mass bled easily and there was a constant dribbling away of cerebro-spinal fluid. The only other malformation was absence of any urethra. H.

Excision of the Superior Cervical Ganglion in Inflammatory Glaucoma.—Dr. M. Lanckton Foster (*Annals of Ophthalmology*, October, 1905) reports a case which commenced as simple glaucoma, and in spite of treatment by eserine progressed until about six months afterwards, when an acute attack supervened for which an iridectomy was performed, but without relief. Eventually the superior cervical ganglion was removed, but the eye continued painful and vision fell to 0. From this case Foster concludes that the presence of inflammatory symptoms of the faintest degree indicates a local condition of the eye productive of glaucoma, which is not dependent on the sympathetic nervous system; while, on the other hand, when we have cases of simple glaucoma which are materially influenced by the removal of the superior cervical ganglion, as indicated by the cases published, we must suppose we are dealing with cases of quite a different nature from chronic inflammatory glaucoma, as maintained by v. Graefe. Foster thinks that most of the published cases were reported after the lapse of too short a time after the operation to permit of reliable deductions as to the permanency of the success. M.

Note.—*A Summary will appear each week in the following sequence:*—(1) "*Recent Medical Literature.*" (2) "*Recent Surgical Literature.*" (3) "*Recent Gynæcological and Obstetrical Literature.*" (4) "*The Recent Literature of Physiology and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

DR. L. T. O.—We cannot advise without being furnished with the full facts of the case. If our correspondent will communicate with us again we will go into the case and report.

X. Y. Z.—There is no public institution of the kind that we know of. The Secretary of the Charity Organisation Society might be able to help our correspondent.

MR. SIMMONDS.—There is nothing unethical in the method proposed to be adopted.

BRADFORD.—The matter should be referred to a solicitor, without delay.

M.D.—The reason is that the parasitic theory of cancer, that is to say malignant disease, is regarded by the best authorities as dead.

SPES.—The answer, unequivocally, is in the negative.

T. B. W.—The latest example is that of Leeds. The public analyst reported that for the quarter ending June 30th out of fourteen samples of butter no less than seven consisted almost wholly of foreign fat.

L. F.—A Paper on "Hernia Through the Foramen of Winslow," by Faure, in the "Bulletin et Mémoire de la Société de Chirurgerie de Paris," No. 12, 1906, gives a capital criticism of the subject.

S. R.—There is a paper on the subject by Drs. Meakin and Wheeler in the *British Medical Journal*, for Nov. 25th last. It will hardly answer all the points you raise, but as the question is yet in its infancy one must suspend judgment.

R.A.M.C.—We can hardly keep pace with the various phases of that blessed word, "mobilisation," but we understand that according to the last plan (Mr. Haldane's) the Nursing Staff will expand automatically with the requirements of the R.A.M.C. A question in Parliament could easily be arranged by one of the Service Members, and might do good by drawing attention to the subject.

T. M. A.—The late Dr. Mark Antony MacDonnell was brother to Sir Antony MacDonnell. He did not practise, we believe, for many years before his death.

F. N. T.—Such a rumour is hardly worthy of notice, but if you are a member of the Medical Defence Union, a letter would probably be written by them on your behalf if the facts were laid before the Council. On the whole, however, we should advise you to wait for a week or two. You will probably hear nothing more of it.

L.D.S.—If you give gas for an unregistered dentist you may probably be charged with "covering." We strongly warn you not to do so. If an unregistered dentist chooses to practise he must settle his own difficulties, and it is not contrary to the humanitarian principles of the profession for you to refuse to help him and his patients, always excepting, of course, grave emergencies of life and death.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 1st.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m. Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Mr. Stuart-Low; Ear.

THURSDAY, AUGUST 2nd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations. Mr. Dunn: Diseases of the Eye.

FRIDAY, AUGUST 3rd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10.30 a.m. Dr. Moullin: Gynæcological Operations. 2 p.m. Medical and Surgical Clinics. 2.15 p.m. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 p.m. X-Rays. Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY, AUGUST 4th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations.

Vacancies.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Manchester Royal Infirmary.—General Superintendent and Secretary. Salary £600 per annum. Applications to the Chairman of the House Committee, Royal Infirmary, Manchester.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, &c. Applications to Albert Edward Booker, Clerk to the Guardians, Union Offices, Westbar, Sheffield.

Weston-super-Mare Hospital. — House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to the Honorary Secretary.

Wolverhampton and Staffordshire General Hospital.—Assistant House Surgeon. Salary £75 per annum, with board, lodging, and washing. Applications to J. Stephen Neil, House Governor and Secretary.

Bracebridge Asylum, Lincolnshire.—Senior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Clerk to the Visitors, W. T. Page, Jun., Esq., Bank Street, Lincoln.

Essex and Colchester General Hospital.—House Physician. Salary £80 per annum, with board, residence, and washing in the Hospital. Applications to Alfred G. Buck, Secretary, the Hospital, Colchester.

The Choriton and Manchester Joint Asylum.—Resident Medical Officer. Salary £120 per annum, with board and residence. Applications to Henry Woodhouse, Clerk to the Joint Committee, Choriton Union Offices, All Saints, Manchester.

Sussex County Hospital, Brighton.—House Physician. Salary £70 per annum, with board and residence in the Hospital, with washing. Applications to the Secretary.

Corporation of Manchester.—Monsall Fever Hospital.—Fourth Medical Assistant. Salary £100 per annum, with board, lodging, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester. Wm. Henry Talbot, Town Clerk, Public Health Office, Town Hall, Manchester.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £75 per annum, with apartments and rations. Applications to S. J. Leonard, Clerk.

Appointments.

ESKELL, L. B., L.D.S., R.C.S.I., Honorary Dental Surgeon to the Winsley Sanatorium for the Consumptives of the Counties of Gloucester, Somerset, and Wiltshire, and the City and County of Bristol.

GOODE, CHRISTINA L., M.B., B.S.Melb., Assistant Medical Superintendent to the Leytonstone Infirmary.

KERRAWALLA, M. P., M.D.Brux., L.R.C.P. and S.Edin., L.M. and S. Assistant House Surgeon to the Hastings, St. Leonards, and East Sussex Hospital.

MOULD, G. T., Major, I.M.S. (retired), Refraction Assistant at the Royal London Ophthalmic Hospital (Moorfields Eye Hospital).

NOALL, W. PAYNTER, M.S.Lond., F.R.C.S.Eng., Clinical Assistant to the Chelsea Hospital for Women.

PORTER, CHARLES, M.D.Edin., Assistant Medical Officer of Health of Leeds.

WALKER, THOMAS WARBURTON, M.B., Ch.B.Vict., Medical Officer to the Workhouse by the Tetbury (Gloucestershire) Board of Guardians.

Births.

GONIN.—On July 29th, at Courtlands, Burstow, Surrey, the wife of E. H. Gonin, M.D., of a daughter.

PURVIS.—On July 21st, at 14 Carlton Crescent, Southampton, the wife of Dr. William Prior Purvis, of a daughter.

Deaths.

COLLINS.—On July 27th, at Hawthorn Lodge, Yapton, John Boniface Collins, M.R.C.S., L.S.A., aged 81 years.

JONES.—On July 25th, at Bron-y-graig, Corris, Merioneth, in his 69th year, John Thomas Jones, M.R.C.S.

TAYLOR.—On July 26th, at Hilldrop, Stevenage, Herts, Deputy-Surgeon-General Edward Taylor, H.M. Bengal Army (retired), aged 81.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, AUGUST 8, 1906. No. 6.

NOTES AND COMMENTS.

Irish Successes in the Army Medical Service Examination.

THE results of the recent examination for commissions in the Royal Army Medical Corps must prove a matter for congratulation to all upholders of the Irish Medical schools. An analysis of the list shows that forty commissions were given, and that of these seven were won by Scottish graduates, thirteen by English graduates, and twenty by Irish graduates. If the list of successful Irish candidates is then examined, it will be seen that three of them obtained their degrees from the Royal University, eight from the Conjoint Royal Colleges, and nine from Dublin University. In view of the fact that on several recent occasions the Trinity College Medical School has been held up to public obloquy as an institution run by an illiterate little coterie, it is interesting to note that at an outside examination its graduates have obtained almost a quarter of the total number of commissions awarded. The Conjoint Colleges have also been the subject of criticism, not alone at the hands of Englishmen, but even at those of Irishmen, and they have been informed from time to time that the value of their degrees is diminishing. It is remarkable then to see that its graduates obtain eight out of a total of forty commissions. We must not overlook the fact that the first place in the examination has been obtained by a pupil of Queen's College, Belfast, and a graduate of the Royal University—Mr. G. H. Stephenson.

An Irregular Election.

A CURIOUS situation arose lately in connection with the election of an honorary surgeon to the Rotherham Hospital. It seems that two honorary surgeons, Dr. Reid and Dr. Knight, retired and offered themselves for re-election. Dr. Reid was re-elected, but when the second name was submitted a member of the Weekly Board suggested that of Dr. Anderson, who was eventually chosen. Now, it appears, that Dr. Anderson had made no application for the post, and that the use of his name was unauthorised, and, moreover, as the meeting at which the election took place was not a general or special meeting, and that being neither it was not competent for a surgeon to be elected. Dr. Anderson consequently tendered his resignation, and the Weekly Board accepted it. The proceedings gave rise to a great deal of local feeling, and a strong meeting of the Governors was held last Saturday week, at which the Weekly Board were censured for their behaviour. Dr. Anderson's conduct seems to have been perfectly correct throughout, and he deserves sympathy for the invidious position in which he was placed.

Mismanagement Charges.

SERIOUS charges of mismanagement of their infirmary have been made against the Salford Board of Guardians. An ex-attendant is said to have asserted that there was a shortage of food, surgical dressings, and clothing; that the staff was insufficient, and that the inmates were unsatisfactorily treated. A great deal of natural indignation has been displayed in the Borough, and an inquiry by the Local Government Board is suggested by the Guardians. Knowing how badly many infirmaries are managed, we should be glad to see drastic action taken against some of the offenders, but, on the other hand, ex-attendants are not always the best witnesses. At any rate, this case calls loudly for the attention of the Local Government Board.

M.B.B.A. (Ambulance!)

THE assumption of the letters M.B.B.A. by a St. John ambulance official, meaning thereby that he is a member of the British Brigade Ambulance, or some such exquisitely tortured reading, was recently noted in these columns. We had imagined that this act of bad taste was attributable to some silly lad, puffed up by the fact that he had passed a real, live examination and obtained a badge. It seemed incredible that a medical man could have deliberately assumed such a misleading gimcrack title. Yet the letter of a Bradford correspondent, himself a member of the medical profession, apparently leaves no doubt in the matter. If so gross a breach of manners has been committed, the local medical men have the vindication of the honour of their cloth in their own hands. It is not for us to indicate the steps that should be taken, but we are strongly of opinion that something should forthwith be done in the matter.

Joint Counties Asylum Censured.

THE visitors of the Joint Counties Asylum at Carmarthen are under a heavy responsibility. Last year after their visit to the asylum, the Lunacy Commissioners reported that there was no proper system for disposal of sewage, alternate exits were not provided, and that owing to defective laundry accommodation, clothes were washed and dried in the wards.

This year the Commissioners found no steps had been taken to remedy these evils. "This condition of things," wrote the Commissioners, "is not creditable to the authorities to whom is entrusted the duty of providing for the care and welfare of the insane of the counties in the union." We should think not, and it is even less creditable when it is due as in this case it appears to be due, to the mutual jealousies and petty differences between the three authorities concerned. Surely the danger to the unfortunate lunatics' health might first be removed, and the quarrels as to who should pay for what be settled afterwards.

LEADING ARTICLE.

THE PASSING OF THE QUACK.

FOR the last quarter of a century at least, the policy of THE MEDICAL PRESS AND CIRCULAR has been directed ceaselessly against quacks and charlatans. Of late, in season and out of season we have conducted a campaign against irregular medical practice and quack medicines so continuously that the doubt has at times arisen in our minds whether the subject might not become a little wearisome to our readers. The matter is one of no less vital importance to the public than it is to the medical profession. Who can estimate, even remotely, the appalling amount of damage to the national health that is effected by the enormous traffic in patent medicines that claim to cure every ill that flesh is heir to? In view of the admitted incurability of many maladies and of the hopelessness of many more in late stages, the public advertisement of claims to cure by given medicines or by specific treatment amounts to a fraud. Nothing is more certain than that the prosecution both of quacks and of nostrum vendors under such circumstances must be followed by conviction and punishment. The exact legal offence thus committed is obtaining money under false pretences, always a serious matter in the eye of British law. The Medical Acts define stringently enough what is the legal status and qualification of a medical man, and when an outsider trespasses in his field and claims to perform medical acts without a proper professional training, the obvious presumption is that he is a fraudulent scoundrel. The wonder is that with these facts staring us in the face, any persons can be found having the assurance to advertise publicly that they are prepared to cure blindness, defects of vision, rheumatism, locomotor ataxy, cancer, neurasthenia, and, in a word, the whole range of maladies known to man! The explanation, however, is, perhaps, not far to seek. The police of the United Kingdom, efficient as they are in keeping order in the streets and in the protection of the property of householders, are, nevertheless, dilatory in the detection of fraud. The public prosecutor's office is, indeed, for the most part a dead letter, and when it comes to the question of prosecuting a bone-setter or other notorious quack, or the vendor of a cure for Bright's disease or cancer, the highly-paid legal gentleman who holds that post is content to twiddle his thumbs. In the rare instances where the police have prosecuted, conviction has almost invariably followed. The week before last, a particularly offensive rascal was laid by the heels at the Stafford Assizes, in the person of "Professor" Richard. In a comparatively short space of time he netted huge sums of money by claiming to cure blindness and many other serious afflictions. Had the police the courage to follow up the imprisonment of this scoundrel by prosecuting the local newspapers who inserted his lying advertisements, for conspiracy to defraud, the whole of the nefarious quack traffic of the United Kingdom would have received practically a death-blow. From the moment that newspaper proprietors refuse to publish the fraudulent advertisements of quacks and quack medicines, the days of both will be numbered. The police have now shown that it is possible to clap a bogus electrical practitioner into prison; what is possible at Stafford can be done all over the kingdom, if only they could be induced to do their duty. "Professor" Richard is a man whose life is said to have consisted of a succession of convictions for criminal acts, and of sentences of imprisonment. An account of his career, given in the *Midland Evening News* for July 27th, shows him to have been engaged in fraud, criminal assault, bigamy, and the heartless deception of women for nearly forty years. The "medical electricity" business was only one of his ways of duping his fellow creatures and extorting money from the public. Yet, though his antecedents must surely have been known to the police, this despicable creature was allowed to travel all over England and swindle the blind and maimed who came to him for treatment. The only creditable fact in connection with the business is that he has been caught at last, and we hope sincerely that his conviction will put heart into the doubting Thomases in command of the public prosecutions. The case is perfectly clear, and the evidence ready to hand. The man who obtains money from people by the pretence that he can cure incurable diseases is amenable to prosecution. Would that "Professor" Richard might light such a candle in England as to consume the whole of his miserable brethren who, naked and unashamed, swindle the sick and suffering in the light of day!

NOTES ON CURRENT TOPICS.

The Choice of a Holiday.

THE summer holiday is usually believed to be a season for recuperation and for renovation; a time when the jaded tissues are able to cast off effete products of over-activity, and to lay in a store of energy for the coming months. If the holiday is to be this, and not a mere new-sensation hunting performance, the choice of the place in which it is to be passed is of great importance. To go to a seaside town or a mountainous district simply because a friend has gone thither and liked it, is not to plan one's holiday scientifically; which

is another way of saying that for a holiday to do one good, the selection of the place where it is to be passed must be determined by the necessities and conditions of the individual. To many delicate women the strong breezes and bracing air of the East Coast cause exhaustion and prostration, while, again, the relaxing atmosphere of some of our sheltered resorts in the South sends the young and vigorous home but little the better for the trip. Especially needful is the exercise of care in advising old people as to their change. To send elderly and overworked men to the high altitudes is to cause them some not inconsiderable danger of apoplexy, and if they are asthmatical or subject to chronic bronchitis, the rarefied air of high mountains may cause ruinous damage to lungs and heart. Climatology as an exact science is yet in its infancy, but it is sufficiently advanced for a well-educated medical man to be able to advise wisely on the choice of a holiday resort and people generally would do well to consult their professional attendant before booking rooms a month or six weeks ahead.

The Nation's Neglect of Science.

Following the example of several of his predecessors in recent years, Professor Ray Lankester in his address at the opening meeting of the British Association on Wednesday last devoted much attention to the national neglect of science. During the last thirty-five years a good deal has been done at our great universities towards recognition of the importance of science, but much is needed before we can be placed on a level with the Germans, our great and chief competitors in the race of national life. We shall surely be beaten in this race unless we wake up and put forth under wise guidance all our powers. The Germans have now a population of nearly 62,000,000 at home against our total of 55,000,000 of European blood in the whole Empire. The greater population equally endowed intellectually and better educated will surely in the end beat the one that is smaller and less well equipped. The Germans have the enormous advantage of a virtually autocratic direction in all the greater matters of government. The central authority secures the best advice and concerts measures, and these are carried out by a thoroughly trained, experienced, and faithful bureaucracy. The people being throughout sufficiently well educated are able to recognise the wisdom and expediency of government proposals, and however impatient of, or opposed to control in other directions, the Germans welcome every ordinance which promises to add to the people's efficiency. The problem with us now seems how to imbue our democracy with a higher spirit capable of adopting lofty ideals. Our people need to be taught what is meant by science—even this they at present do not understand—and then they need to be made to comprehend what is meant by scientific research. It is difficult to make the people understand the utility of the pursuit of pure science or to recognise the value of those who labour at it. They cannot comprehend the object of work devoted to accumulation of facts which seem to them to have no relation to any utilitarian purpose. They need to be shown that all great, practical advances in arts and manufactures have been always based upon discoveries made with the sole aim of investigating the phenomena and increasing our knowledge of nature and without any dominant thought about any useful purpose to which the new facts might be made to contribute.

Canadian Medical Journal.

In anticipation of the visit of the British Medical Association, the *Canadian Journal of Medicine and Surgery* has published a special number which does equal credit to the enterprise of its editor and the resources of medical journalism in the Colony. It is beautifully printed on a specially-coated paper and contains no less than forty pages of half-tone reproductions of the medical institutions of Toronto, the University buildings, glimpses of Canadian scenery, and portraits of well-known British and Canadian physicians and surgeons. We confess to a feeling of envy as we gaze at some of the hospital and university buildings and compare them mentally with our own. Whatever our hospitals may have to recommend them in the way of tradition and association it is impossible not to turn with something like a sigh towards such handsome buildings as the Toronto General Hospital and Dr. Meyers' Hospital for Nervous Diseases and wonder whether our own sick would not do better in these noble institutions with their beautiful surroundings. One picture that especially impresses itself on our mind is that of the summer quarters of the Hospital for Sick Children, Hanlan's Point, Toronto. There we see a charmingly inviting building surrounded by trees on the edge of a lake, on which latter the nurses are rowing the children about. The new Medical Buildings, Queen's Park, are very handsome; they are modern in the sense of embodying all the requirements of light and fresh air, yet there is a suggestion of an Eastern mosque about them which lends a touch of romance to a structure which over here would probably have consisted of four walls and a roof. We are introduced, also, to some of the public buildings of Toronto, which show the same regard for beauty and utility, and we close the number with the feeling that if our race is able thus to perpetuate all that is good in the mother-country and to recast it in new surroundings with such admirable results, the future of the Empire is in safe hands.

Sanitary Leather.

A noticeable feature of the recent Congress of the Sanitary Institute at Bristol was the amount of interest it occasioned among newspaper readers; that is, if one may judge by the amount of space devoted to the proceedings of the

Congress by the daily press. It is therefore, all the more necessary that the papers read at such meetings should be kept at a high level and should give no opening for the pen of the scoffer. This remark is prompted by the fact that a certain paper—doubtless an admirable one in itself—dealing with the adulteration of leather, has been made the subject of jesting comment by several journals. To argue that the adulteration of leather with glucose or Epsom salts had no bearing on the public health would be to misapprehend the full meaning of the term "hygiene," but surely a paper on the subject would be more acceptable at a gathering of manufacturers or a meeting of Chambers of Commerce than at a Sanitary Congress. Hygiene comprehends everything bearing on health, and as no circumstance or condition to be found in the universe has not some direct or remote bearing on health, hygiene and omniscience come to be very closely related. In fact, we are reminded of a remark once made by Sir Michael Foster, that if some artificial bounds were not set to the scope of anatomy as taught at Cambridge, it would soon be found that the religions of the world formed but a small part of the knowledge required of medical students in their second M.B. There are surely sufficient important matters more closely related to public health that might be discussed in a section of physics, chemistry, and biology than how far it is safe to walk in cheap boots, and what proportion of their weight these articles lose if the wearer steps into a puddle.

Herbalist Conference.

IT may come as news to many of our readers to learn that the people who call themselves "Herbalists" wish to be taken very seriously. They have just held a conference at Nottingham with the object of organising a college or "Physio-medical University," for the United Kingdom. Two American "herbalists" of renown in their own country came over to tell their British brethren how the great heart of the American continent beats in sympathy with the aspirations of their unrecognised brethren in the British Isles. It seems that "herbalism" has secured a position of such dignity in the States as not only to possess physio-medical colleges but even professors, and the National Association of Medical Herbalists of Great Britain listened with bated breath and watering mouth to the stories of the good times enjoyed in America as told by Professor Thurston, of Indiana, U.S.A., and Dr. J. W. Stockey, of Columbus, Ohio. Mr. Marlow, who welcomed the delegates to Nottingham, gave an address, which, for pure "cheek," would, we think, take a lot of beating. He told his audience that "the herbalists' field was the world, and that while claiming the right to use its remedies, they allowed the same right to others. The system adopted by the Association had done more to revolutionise the medical world than any other. *He asked them to strive to keep the medical profession upright and noble.*" We have taken the liberty of putting the last sentence in italics, for, coming as it does from a member of a body of men whose principal function seems to be to sell "worm-powders" to the poor, it strikes us as reaching a height of impertinence that we have seldom seen attained before. The conference debated the subject of promoting a Bill in Parliament to legalise their calling, and finally decided to petition the Privy Council for a charter of incorporation. We fancy that there is little chance of the lords of that august body entertaining any such grotesque proposal.

Inspection of Food.

IN view of the impossibility of safeguarding the purity of food under the present laws, it would seem almost better that these unworkable Acts should be repealed. Under existing conditions, a great part of the public are the victims of misplaced confidence. They imagine that laws once added to the statute book are somehow automatically enforced, and they do not understand that it entirely depends upon the activity and vigilance of local governing bodies as to whether adulteration shall be checked or any supervision whatever exercised to ensure the wholesomeness of the meat, fish, and milk, purveyed in their district. In many places, especially where a certain class of tradesmen dominate the authority, food Acts are either completely neglected or so partially worked as merely to give a false sense of security. It will surprise many readers to learn that even yet there has been no proper arrangement made for the inspection of food entering London, or for public slaughter-houses where control over the meat supply can be exercised.

National League of Physical Education.

A SUCCESSFUL meeting of the National League of Physical Education was recently held at Sir Weetman Pearson's house. The Lord Chief Justice, President of the League, was in the chair, and he was supported by the Bishop of Ripon, Mr. Birrell, Professor Howard Marsh and others. Lord Alverstone spoke of the progress the League was making and earnestly implored his audience not only to devote themselves to the task of improving as far as possible the breed of the English race, but to interest all whom they could influence in this great national question. The Bishop of Ripon and the other speakers all congratulated the Minister for Education on the concession he had made to professional opinion in offering to make medical inspection compulsory in elementary schools, and Mr. Birrell himself confessed he was astonished at the unanimity displayed in the House when the matter was before it. Professor Howard Marsh in warmly supporting all that had been said in favour of medical inspection, allowed himself to go so far as to say that in about ten years we might expect to see infectious diseases banished from the land. For ourselves, we cannot but regret such sweeping prognostications. All

medical men hope that efficient medical inspection may considerably reduce the number of cases of infectious disease among school children, but it is rash in the extreme to expect such cases to disappear altogether. Similar statements have been made in the past, notably at the introduction of isolation hospitals, and they have always been falsified in the event. The only safe rule with regard to prognosis is not to prophesy till you know.

Boric Acid in Food.

The physiological action of boracic acid upon the human body has of late years assumed an important place in public health administration. It has been found as a preservative in milk, cream, and a long array of foodstuffs, especially in hermetically-sealed preparations. Although the precise action of the drug in question has perhaps not been quite adequately ascertained, there can be little doubt that the decision to condemn its presence as an adulterant is upon the whole a wise one. So long ago as 1888, Mr. A. H. Marsh published an account of a case in which boric acid crystals were found in the urine of a patient who had been taking 80 grains of boric acid daily for three days. On evaporation, crystals were found, and on adding spirit to the residue a characteristic green flame was obtained by ignition. The urine was kept in an uncorked bottle for three weeks, and at the end of that time it contained no organisms and was free from disagreeable odour. The cystitis from which the patient was suffering underwent considerable improvement. From various points of view this case is well worth recalling. The general trend of medical opinion nowadays is in favour of the harmfulness of boracic acid. Among children certain deaths have been definitely attributed to its presence as a preservative in cream.

Higher Education in Ireland.

In view of the forthcoming meetings of the Commission appointed to inquire into the affairs of Trinity College, Dublin, and Dublin University, the subject of higher education in Ireland has again come into prominence. Three important documents have appeared in the daily press during the past week. The first is a copy of a correspondence between Archbishop Walshe and Mr. George Fottrell, in which the latter asks whether the Roman Catholic Hierarchy would approve of a scheme whereby, provided it granted the necessary concessions, Trinity College should become a national college acceptable to Roman Catholics. The second document consisted of a statement by certain Fellows and Professors of Trinity College, submitting and approving of the scheme which had been mentioned by Mr. Fottrell in his letter to the Archbishop. The third document consists of a statement of the Episcopal Standing committee of the Roman Catholic Church, and in it the latter body "feels that it is safe in stating that the Catholics of Ireland would be prepared to accept any of the following solutions:—(1) A University for Catholics; (2) a new college in the University of Dublin; (3) a new College in the Royal University; but that on no account would they accept any scheme of Mixed Education in Trinity College, Dublin." We cannot here enter into the merits and demerits of the scheme proposed by certain Fellows and Professors and condemned by the Catholic Hierarchy. It will be discussed to the fullest extent before the Commission. As one who desires that the verdict of the Commission may be uninfluenced by the rancour engendered by diverse politics and religions, we venture to express the hope that, whatever solution is reached, it will be one which will place higher education in Ireland outside the control and influence of clerical authority of any denomination, and equally outside political strife. Further that it will be one which, so far from setting up two rival educational bodies in a land already sufficiently divided, will bring the youth of Ireland together during the most adaptable periods of their lives. Such a settlement of the educational question will undoubtedly be opposed by the professional politician, but we cannot believe that it will not commend itself to conscientious and far-seeing men of every class.

PERSONAL.

Dr. R. C. Brown, of Preston, has given £150 per annum for two years for a pathological scholarship in connection with the investigations being carried out by the committee of rheumatoid arthritis and allied diseases at Cambridge University.

At Liverpool, on July 29th, Superintendent Stowell, on behalf of the officers and constables of F Division presented to Dr. A. F. Walker, police surgeon, a barometer suitably inscribed and a dozen silver teaspoons for Mrs. Walker on the occasion of their marriage.

Dr. T. A. Starkey has just had a distinguished honour conferred upon him, that of being the first scientist of the American continent to be elected to a fellowship of the Royal Sanitary Institute. Dr. Starkey is the head of the Department of Hygiene of the McGill University.

Five hundred English medical men are visiting Canada for the British Medical Association meeting. They will meet there no less than 1,500 Canadian delegates.

Amongst British physicians who will make the journey are Sir William Broadbent, Sir Thomas Barlow, Professor Osler, and Sir James Barr.

Sir Hector Cameron and Sir Victor Horsley will be among the surgeons, and the physiological representatives will include Professor Halliburton and Professor Sherrington.

Mr. Walter Emden's Scholarship of £100 for the best original work produced in the laboratories of the Middlesex Hospital has this year been awarded to Dr. Victor Bonney.

It is reported that at the meeting of the British Medical Association at Exeter next year, Dr. Davy will be President of the Association.

A CLINICAL LECTURE
ON THE
THE CONNECTION BETWEEN TUBERCULOSIS AND SYPHILIS.

By JONATHAN HUTCHINSON, LL.D.Oxon., Hon.M.D.Dub., F.R.C.S., F.R.S.,
Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and Royal London Ophthalmic Hospital.

GENTLEMEN,—Our subject to-day is "The Connection between Tuberculosis and Syphilis," and I think it would be convenient if we endeavoured to establish a few general principles, rather than go into detail on any one point. You can easily interpret the principles and apply them.

The manifestations of syphilis are very variable, although the majority of cases are tolerably alike. If we were told that a man had suffered from syphilis, we should know that he had had chancre and an eruption, and we should be able to tell the character of the eruption. That is in reference to the general run of cases. But there are cases of syphilis which substantially differ from those in which the disease commonly manifests itself. One man, instead of having a papillary eruption, in syphilis, may develop a bullous eruption, or be covered with psoriasis, and so on. In the later stages of the disease a patient may develop a lupoid eruption: instead of the early eruption fading away satisfactorily under ordinary treatment, he shows a tendency to have a sore on his skin, which persists for a long time, resembling the ordinary form of tubercular eruption.

What is the law by which we shall seek to interpret these remarkable differences? I think we shall be willing to admit that the virus, in all probability, is always the same. In recent years we have got a good deal of evidence as to what that virus is, and we believe we have reason to infer that there must be, in such a specific and peculiar disease as syphilis, a specific virus to explain the phenomena present in a patient who is suffering from it. Some living virus is introduced into the blood at the time of contagion, and is multiplied in the blood, and produces the various features that characterise the disease. That inference has been recently confirmed very remarkably by the discovery of a spirochæte, a protozoan, not a vegetable thing, but more like animal life, which, if introduced into the blood, gives rise to syphilitic phenomena. In past times some authorities held that the different forms of eruption, in syphilis, had to do with different forms of poison which had been introduced into the system. Without going far into argument upon that question, the evidence that we have would go to show that the virus of syphilis is one and the same in all cases. We find, in populations in which syphilis is existent, that single individuals manifest one peculiarity of eruption, and other single individuals manifest another. We cannot believe that, in syphilis, in England, there can be any remarkable difference in the virus; if there were, we should have a little epidemic of one kind and another, in connection with the disease.

To account for the differences which are sometimes manifested, I think we may reasonably point to a well acknowledged fact, namely, that individual men do not exactly correspond in all their proclivities. It is individual peculiarity in the recipient of the poison—not in the poison—which accounts for all the differences of syphilis. Then again, there may be differences manifested in the disease which are due not so much to the virus itself, as to the specific remedy employed. One patient, for instance, cannot take mercury in large quantities, and another can; one man may be able to take sufficient mercury to kill the spirochæte, whereas another cannot take enough to destroy the parasite. And so the remedies employed will often give mixed results. But, quite apart from the influence or non-influence of treatment, we may assume that the peculiarities in individuals who contract syphilis account for the peculiarities in its manifestations.

In reference to peculiarities in individuals, I may say that we must believe that many persons have only a quite latent, quite concealed, but still a very distinct proclivity to certain diseases. Take, for instance, the eruption of psoriasis, common psoriasis, which occurs in persons of very fair health. We are not aware of any special influence which produces it. Patients who get psoriasis have some proclivity towards it which we cannot detect. There may be a peculiarity in a person which does not show itself at once, but yet there is in the skin a tendency to produce those scales and patches which characterise this particular affection, a tendency which renders him liable to nothing else at all. So that there is an innate tendency to psoriasis. I need not tell anyone that when once the proclivity to psoriasis has shown itself it lasts through the patient's lifetime. You give him arsenic and he gets rid of the eruption, but it comes back again. Pemphigus is a disease met with in persons who are apparently in good health. Suddenly a man becomes covered with bullæ characteristic of pemphigus. So also as regards many other forms of skin disease. The proclivity to papillary gout exists in a very large section of the British population, though, I believe, it is diminishing every year. A great many people are born with a tendency to that form of gout, though the tendency varies in different individuals. Then there is also a proclivity for the skin, when inflamed, to let its papillæ grow, and such a condition in any person makes him liable to lichen or acne, which are both affections of the glands connected with the suppressed hairs on the skin. Or a person with papillary growth may develop warts.

A very peculiar form of syphilis is developed in the Tropics, and occurs occasionally in England, producing a tendency in individuals towards papillary hypertrophy. The syphilitic poison, having been introduced into the blood, causes not only inflammation and eruptions due to congestion and exudation in various parts of the tissues of the skin, but produces actual growth. It is a very peculiar fact indeed. For instance, at the back of the tongue of patients passing through the secondary stage of syphilis, you may frequently see a very definite development of papillary warts. Something in the spirochæte seems to stimulate papillary growth. To this condition of papillary growth which is a common manifestation of syphilis in the Tropics, especially in the West Indies and East Indies, various names have been given. It is sometimes described in books as Framboesial syphilis, and tends, more than other forms, to the development of papillary growth. I do not think it has any definite or special connection with hot countries—typical cases occur in this country as well as in the Tropics—but it reveals a tendency in the individual, which may be a tendency in the family or in the race, to papillomatous growth in syphilis.

I have made these introductory remarks in order to come down to our more definite subject, *the connection between tuberculosis and syphilis*. May we just speculate a little upon what is likely to happen when a person who has the tubercle bacillus in his blood happens to contract syphilis. Will the syphilis run its ordinary course? or will it rouse the tubercle

(a) Lecture delivered at the London Hospital, June 19, 1906.

bacillus to action? or will it leave the tubercle bacillus quite alone? When they meet in the blood, will they stimulate each other towards producing any further kind of result? In the primary stage of syphilis, I think, it is not probable that a phthisical patient will encounter any difference at all; probably he will be very much the same in the early stages. The tubercle bacillus is almost ubiquitous, it is present in nearly everybody, but it is, more or less, kept latent, and there is plenty of evidence to show that it does not develop until some influence is exerted which excites it into action. So that we will not be surprised if a patient, having contracted syphilis, may manifest certain symptoms indicating that he has also tuberculosis, although he has not shown these symptoms before. Here let me introduce the doctrine, which may be familiar to some, of what is called symbiosis, and which signifies *two lives united in one*. In botany you have an illustration of this doctrine in the union of two quite different plants which grow into each other, the one stimulating the other; and when that occurs, it produces a third being called a lichen. It is highly probable that this process of symbiosis goes on in a great number of different forms. Many things live together and produce results quite different. I thinkit is very likely that the tubercle bacillus and the poison of syphilis can in some way unite symbiotically and produce a third condition which is not characteristic of either one of them. There is such a thing as a recurrent chancre. A person, say, has suffered from syphilis four, five, six, or seven years ago, and then the scar left on his penis, where the chancre was, and which has been perfectly quiescent for that time, takes on an induration which is exactly like the original. There is a means, however, of distinguishing it from the original. A primary chancre contracted, for instance, by contagion from a sore, almost always begins by an abrasion of the surface. The scar of an old chancre does not begin on the surface, but under the surface by the development of induration. In primary chancre the induration is secondary to a certain amount of abrasion, and the patient has this peculiar induration lasting perhaps for many months and very difficult to treat, but eventually yielding to treatment. For some years we have been conversant with this class of recurrent induration which I have mentioned. You never see either it or primary induration except in people who are syphilitic. My reason for insisting on this point is in order to mention a recent fact which has come to my own knowledge bearing upon the doctrine that I have already called your attention to, the doctrine of symbiosis, according to which the union of the tubercle bacillus with the poison of syphilis is a possible contingency. A gentleman came to me, whom I had treated some six years before for syphilis. I had known him well for several years. He came to me with a hard, conspicuous induration on the free margin of his prepuce. I thought it was a chancre; only, the patient seemed to be in perfect health. However, knowing how difficult it was to get that sort of growth to disappear, and also being very much interested in the development of our knowledge as regards the presence of the spirochæte in syphilis, we were very anxious to know whether the spirochæte was present. Accordingly, I told him to get the growth cut off. He said, "Yes, have it cut off for microscopical examination"; and so he was circumcised and the whole of the induration was taken away. I sent the prepuce to the Clinical Investigation Department, and it was examined by a very experienced microscopist. I told him that I wanted to know whether the spirochæte was there. To my astonishment I got a report back, stating that the induration was not syphilitic at all, but that it was a very recent infection of tuberculosis. He had found the tubercle bacillus, but could not find the spirochæte at all. When I expressed my astonishment at what he had stated, he said, "If you do not believe it, show the thing to somebody else." I did show it to several persons skilled in microscopical matters, and they also said that it was tubercular. This confirms my theory that in connection with syphilitic scars, conditions which are characteristic of tuberculosis may be produced, and that syphilitic forms of inflammation may be associated with recent tuberculosis.

We come to the next topic, which is, the disease known as lupus. I daresay that most of you are conversant with the appearance of common lupus, which is supposed to be always in connection with tuberculosis. The disease known as lupus is chronic inflammation of the skin, tending to thicken and to the formation of granulomatous tissue. A good deal of soft tissue forms, and there is a tendency to ulceration and a tendency to spread. Lupus is always worst in cold weather, and occurs in delicate patients, and it is clearly infective in the patients themselves, because it travels from part to part.

My next point is that there is, in connection with syphilis, an eruption which is exactly like lupus. This eruption occurs, not in the secondary, but in the tertiary stage, in the form of gumma of the skin. It is a granulomatous formation in the skin, in connection with syphilis, which spreads like the ordinary forms of tubercular lupus. I use the term *tubercular* when the lupus forms in association with the tubercle bacillus. When, on the other hand the lupoid skin, though it may simulate tuberculosis, is associated only with syphilis, I make use of the term *syphilitic*. A skilful dermatologist will tell you whether a given case of lupus is syphilitic or tubercular, but very often, to the ordinary observer, syphilis is exactly like tuberculosis. There are, however, certain differences by which you can generally diagnose the one form of lupus from the other. In connection with tubercular lupus there is a sort of brown, semi-transparent thickening of the skin, exactly like brown jelly. That often shows considerable thickness. You do not get such thick masses of it in the forms of syphilitic ulceration which simulate tubercular lupus. In tubercular lupus the general spreading is slow; in the syphilitic form it is more rapid, and there is also more tendency to inflammation and the formation of crusts.

As regards this disease which we call syphilitic lupus—a name to which many of my friends would strongly object—my suggestion is that the disease is really a combination of two things occurring in a patient. It is the presence of the tubercle bacillus which gives the tendency to the syphilis to spread. Why should only one patient in a hundred of those suffering from syphilis have got any syphilitic lupoid disease? This disease would be far more common than it is, if it were the direct result of syphilis. My own impression is that syphilitic patients who have the tubercle bacillus suffer more frequently from tubercular lupus.

One means commonly adopted in the treatment of syphilis is to give iodide of potassium and mercury. It is held that mercury kills not only the spirochæte, but the tubercle bacillus. A very skilful physician, in olden times, used to give small doses of mercury to cure phthisis and all tubercular affections. The same treatment is beneficial in syphilis, and if tonics be combined it may be useful in tuberculosis and lupus. But I think the most efficient plan of treatment for syphilitic lupus and tubercular lupus is to entirely destroy the tissue which is affected, using either the actual cautery or chemical cauterization.

There are a great many remarkable coincidences of similarity between these two forms of disease, and in cases of syphilitic lupus there is often a history of tuberculosis. I constantly ask my patients who have forms of syphilitic lupus whether there is a history of tuberculosis, either threatened or actual, in the family. I remember having a patient, a man, very much worn out in health, and a typical example of syphilitic lupus in its severe form. I said to him, "What is the history of your relatives? What have they died of? Have you any brothers and sisters?" "No, all have died of consumption. He himself had been threatened by that disease, and his statement illustrates a well-known fact, that a great many of

those who suffer from syphilitic lupus have a history of tuberculosis either in themselves or in their families.

Are there any other forms of disease in which the tubercle bacillus unites with the syphilitic virus? Although I do not find that patients with syphilis come to me because they suspect themselves as being phthisical, nevertheless I have seen a great number of syphilitic patients suffering from phthisis. It is extremely frequent for syphilis to pass into phthisis. I remember one marked case in which a student who had syphilis became phthisical and died. That is almost the only case of the kind that has fixed itself on my memory.

Syphilitic gumma is also a disease with which tubercle may be associated, though very rarely does that happen. I am trusting to the testimony of eminent pathologists who have collected a large amount of evidence on the subject. A very distinguished pathologist in Guy's Hospital informed me that very rarely indeed had he found tuberculosis in association with syphilitic gumma.

Gland disease is often found quite definitely in connection with syphilis. I remember one case in which a woman had been under my care for some time with gland abscesses in her neck. The case occurred in those days when we did not think of excising diseased glands. I did not think the patient was syphilitic, but that she was tuberculous. Finally she brought me her latest child, and I traced evidence of this child being syphilitic. I afterwards saw two of the other children, who confirmed the fact of the existence of syphilis in that woman's children. I had treated her for a long time as being a tuberculous case, but in her case there was a tendency to suppuration, such as occurs in syphilis.

There is a very interesting condition of perforation of the septum of the nose which may occur in syphilis. But it has now been ascertained as an established fact that there is a tubercular affection of the septum of the nose which exactly simulates syphilis, but is not connected with syphilis at all.

I have been dealing hitherto with acquired syphilis. I ought also to have said something as regards hereditary syphilis. I do not know of any very definite examples of cases in which patients with a tuberculous tendency have suffered from hereditary syphilis. But it is very possible that patients who inherit a tendency to tuberculosis may inherit at the same time the poison of syphilis, and in these cases mixed results may ensue, as, for instance, syphilitic scrofula. In olden days all forms of scrofula were considered to be syphilitic, but in the present day we believe that a great deal of what is called scrofula is chronic gland disease, and has no taint of syphilis at all. Though the two things may resemble each other very closely they are not really related, and certainly one may occur without the other. But I have known cases in which the conditions usually termed struma were very probably the results of syphilis.

The principles, therefore, which I lay down in connection with our subject are these:—Tendencies to disease are very often latent; these tendencies may be modified by the introduction of syphilitic poison; and this poison may subsequently exert its influence not quite definitely in the same manner that it would have done if there had been no previous hereditary poclivity, but when found in association with this proclivity, it may give mixed results. I believe that these principles interpret a great many conditions, in connection with syphilis, which it would otherwise be difficult to diagnose.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Jonathan Hutchinson, LL.D., Oxon. and Cantab., Hon. M.D. Dub., F.R.C.S. Eng., F.R.S, Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and the Royal London Ophthalmic Hospital on "Diseases of the Skin Caused by Insects," delivered at the London Hospital, July 3rd, 1906.*

ORIGINAL PAPERS.

THE HÆMOPTYSIS OF TUBERCULOUS SUBJECTS.

By G. LEMOINE, M.D.

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HÆMOPTYSIS due to pulmonary tuberculosis is by far the commonest form met with in practice, and if only on account of its importance, deserves to be dealt with separately and discussed in its different aspects according to the stage of the disease at which it makes its appearance. We recognise, of course, that hæmoptysismay be dependent on other causes than tuberculosis; but these non-tuberculous cases are extremely rare, so rare indeed, and these few so open to suspicion, that, speaking generally, it may be asserted that nearly all cases of hæmoptysis, however scanty or ephemeral, are more or less associated with tuberculosis.

Laennec, Trousseau and other observers, it is true, asserted that at least half the cases of hæmoptysis were due to some other cause than tuberculosis; but this opinion was based on the assumption that, as many of the patients did not subsequently develop tuberculosis, they were therefore not tuberculous, whereas we now know that it is quite possible to be tuberculous without becoming phthisical.

From a clinical point of view the cases must be subdivided, not only in regard to prognosis, but also in respect of treatment. We shall therefore divide them into three groups. (1) The premonitory hæmoptysis that appears before the local signs of pulmonary tuberculosis have become manifest. (2) Hæmoptysis of the congestive period, occurring at a stage when the signs of pulmonary tuberculosis can be detected. (3) Terminal hæmoptysis met with during the period of ulceration and the formation of cavities.

PREMONITORY HÆMOPTYSIS.—I will read you the notes of a very typical instance of this form of hæmoptysis: A young man, aged 18 strong, robust and addicted to athletic pursuits, was suddenly seized with hæmoptysis one evening about two hours after dinner. It came on suddenly, without obvious cause; he began to cough and then expectorated blood-stained sputum in considerable quantity; in fact during the night he expectorated a small tumblerful. On the following day the hæmorrhage had ceased but forty-eight hours later the cough returned, and again he spat blood, after which the attack came to an end. The attack ran its course in three days without fever and without any obvious lesion. During the attack stethoscopic examination revealed some dulness of the respiratory murmur and roughness on inspiration. The chest was resonant, and no mucous or sub-crepitant râles could be heard. Even these trifling symptoms had disappeared at the end of the week.

We have to ask ourselves whether this apparently robust young man was, in reality, in good health when attacked by hæmoptysis. We elicited from his family that for several weeks preceding the attack he had been indulging to the full in all sorts of athletic pursuits, dining out almost every evening, going to dances, in short he had been leading a very active existence. For some days previously, however, he had not

been feeling quite well, complaining of lassitude and general malaise, with loss of appetite, in spite of which he had been leading a more fatiguing life than ever.

Everything having returned to normal our patient resumed his previous mode of life and continued to remain in excellent health, in fact he did his military service two years later and was certified as robust. Two months after returning to his regiment he had a fresh attack of hæmoptysis which, this time, lasted a fortnight, with an evening temperature between 99° and 101°F. The hæmoptysis ceased, but on auscultation a congested area undergoing softening was discovered on the right side of the chest, and at present he is under treatment in a southern town with one apex breaking down, and the disease is progressing rapidly.

Here is another example, that of a young woman in whom the hæmoptysis was thought to be "vicarious." She was twenty-two years of age, and had for some time been feeling tired and languid. She spat small quantities of blood from time to time at her menstrual periods. As she coughed her lungs were examined, but nothing was discovered beyond a little respiratory roughness. Two days later nothing whatever was audible, there was no cough, no blood spitting. It was thought that the blood might be merely complementary to deficient menstrual flow, what is known, in fact, as supplementary hæmoptysis. By supplementary we mean a discharge of blood that has been deviated from its normal course and escapes *via* the lungs. In the great majority of instances vicarious menstruation takes place *via* the lungs, and most of us have, at one time or another, met with instances of the kind. I remember a case at La Salpetrière, a woman who for forty-two years had sharp bleeding from the lungs at her menstrual periods consequent upon sudden arrest of the menses; also the case of a woman sixty years of age who had never menstruated *per vias naturales*. How can we explain this catamenial hæmoptysis? In all probability the suppression of the menses is not the cause but the effect of a pre-existing tuberculosis, the menstrual hæmoptysis being the consequence of a monthly congestion in and around the tubercles. Moreover, women who exhibit this vicarious menstruation may, and often do, become tuberculous. What are we to conclude from all this? I think we must admit that there exists such a thing as vicarious menstruation, but we must nevertheless be on our guard when we have to deal with girls who menstruate *via* the lungs. Such menstruation ought only to be classed as vicarious when after careful examinations repeated at long intervals we have convinced ourselves that the lungs are intact.

But how can we distinguish between this catamenial hæmoptysis and essential symptomatic hæmoptysis? Well, menstrual hæmoptysis is copious—a quart or more of blood each month, while essential hæmoptysis is a recurrent phenomenon, we have to-day a few blood-streaked expectorations, to-morrow nothing, the quiescent period may last for hours or even days, and then the blood-spitting recurs. The first variety then comprises a sudden outrush of blood and nothing between the periods, no blood-stained expectoration, and the general health is unaffected. This catamenial hæmoptysis is most frequently seen in hysterical, neuropathic and hypochondriacal subjects. To come back to my patient, two years later she had a fresh attack and this inaugurated unquestionable tuberculosis.

Here is a third observation of the kind. This was an arthritic subject who, on making a violent effort, spat blood. On auscultation one apex was found to be consolidated. Things returned to normal a few days later. Here we have to ask ourselves whether the hæmoptysis was due to the arthritism or whether there was a latent tuberculous lesion.

The arthritic subject, you must remember, manifests congestive tendencies. This congestive tendency may manifest itself anywhere, and the hæmoptysis may, as a matter of fact, be due to arthritic congestion localised in the lung. We recognise arthritic hæmoptysis by its sudden onset, its rapid disappearance, its relationship to barometric variations, and by the fact that it usually supervenes at night. Dr. Huchard, who has fully described the arthritic variety of hæmoptysis, only relates one case, and it is the only one in which an autopsy had been made. The subject was not tuberculous, it is true, but, on the other hand, the evidence of arthritism was not very clear either—in short, hæmoptysis of arthritic origin does not so far repose on any very conclusive basis of fact.

I have described three varieties of unexpected hæmoptysis occurring in apparently healthy subjects. The prognosis is benign in the premonitory cases if the patient is intelligent, is willing to do what he is told and is attended by a practitioner who knows how to deal with such a case.

And now as to treatment. The practitioner will have to choose from the many medications recommended in the treatment of hæmoptysis those whose action is least uncertain and most rapid. Rest in bed is the first step, with absolute repose, even talking to be forbidden. Internally there is nothing better than ergotine, which acts by constricting the vessels. This may be given either by the mouth or hypodermically. Mustard plasters or poultices may be applied night and morning to the affected side, and an aloes pill (gr. 2 or 3) should be given daily. Hot foot-baths at midday and evening, iced drinks, and so on.

Hæmoptysis at a More Advanced Stage.—Hæmoptysis at this period is easy to diagnose. You find dulness over the apex, vocal fremitus is accentuated and inspiration rough, this settles the question of tuberculosis. Hæmoptysis is always possible in such patients, and this early hæmoptysis is characterised by the following symptoms: a dry cough two or three days before the attack, a tendency to shivering, to sweating, to fever, then, suddenly, in the midst of this discomfort, the cough becomes more troublesome and blood is coughed up, it may be in considerable quantities. If you examine your patient at this juncture, in addition to the stethoscopic signs just enumerated, you will hear sub-crepitant rales indicative of a tolerably severe congestion. The hæmoptysis may last a week or more, and is accompanied by a marked rise of temperature which may last as long as the congestion. This variety of hæmoptysis often causes anxiety by reason of its copiousness and its tendency to recurrence, constituting what is called hæmoptoïc phthisis.

Certain authors who did not appreciate the importance of the signs of incipient tuberculosis, promulgated the odd view that tuberculosis might be the consequence of hæmoptysis, the so-called *phthisis ab hæmoptoë*. To accept such an explanation we should first, says Debove, have to discover, in this hæmoptysis reputed to be the precursor of phthisis, some conceivable cause other than tuberculosis.

Now, thanks to modern researches, we are in a position to assert that hæmoptysis is never anything but the earliest sign of the disease, for in the expectorated blood Hiller has identified the tubercle bacillus, and was thereby led to conclude that the hæmoptysis was the effect and not the cause of the tuberculosis. The treatment of this form of tuberculosis is, in general, the same as that already described, and it is often successful in arresting the hæmorrhage and the tuberculosis, provided the patient can and will adopt suitable measures.

HÆMOPTYSIS OF THE PERIOD OF CAVITY FORMATION.—This form of hæmoptysis is less frequent than that just mentioned. It is, however, more copious and entails greater immediate danger. It takes place at the period of breaking down of the areas of consolidation and the blood is derived from the cavities. The rupture of vessels in these hæmorrhages seems to be the consequence, on the one hand, of the obliteration of a certain number of twigs of the pulmonary artery by interstitial sclerosis developing in the walls of the cavity; on the other hand of a rise of blood pressure in the pulmonary vessels that have remained patent and have become more fragile as the result of inflammatory-degeneration and deprivation of their natural support following upon the destruction of the pulmonary parenchyma.

Hæmoptysis at this period may occur in one of two forms, as red masses mixed with matter or as pure blood. In some instances there is merely a sanguineous exudation from tissues undergoing softening, or the hæmoptysis may come from the neighbouring zone of congestion in which event it may be copious, possibly even immediately fatal.

Hæmoptysis at the period under consideration varies in prognosis according as there is or is not fever. If febrile the disease is gaining ground, and the activity of the micro-organism is intensified. These hæmorrhages are very grave, and indicate the onset of an acute period, which will soon culminate in the destruction of the patient. In the absence of fever the prognosis is favourable, the hæmoptysis being regarded as a local accident without bearing on the general health.

At a still more advanced period patients may have hæmoptysis with each outburst of congestion consequent upon the rupture of vessels in the neighbourhood of the cavities. When hæmoptysis follows rupture of one of these vessels the blood escapes from the mouth in large quantities, three, six, or ten ounces at a time; the patient is seized with fear at the sight of the blood, he becomes pallid, there is tremor, acceleration of the pulse and then a final syncope closes the scene.

The treatment of these cases varies according as there is or is not associated fever. Febrile hæmoptysis must be dealt with on the same lines as the premonitory hæmoptysis. The patient should be placed in a cool and well-ventilated room, in a semi-reclining position, the head resting on a horse-hair pillow. He must avoid efforts of every kind, should, as far as possible, refrain from coughing and remain perfectly quiet and silent. To begin with he must only take iced drinks. Counter-irritation by dry cupping and mustard plasters, very hot foot-baths twice daily. Ergotine should be injected hypodermically at once (Tanret's ergotinine 1-100th to 1-50th grain), or injections of adrenaline in doses of 1-100 grain daily. Ergotine and adrenaline only act on vessels provided with a non-striated muscular coat, which is not present in the pulmonary capillaries. We must, therefore, give emetics, such as ipecacuanha and tartar emetic. The active use of emetics, which were popularised by Trosseau, is remarkably hæmostatic.

QUACKERY, OTHERWISE HUMBUG.

ABSTRACT OF GRADUATION ADDRESS AT EDINBURGH UNIVERSITY.

By THOMAS ANNANDALE, F.R.C.S.,

Professor of Surgery in the University of Edinburgh, &c.. &c.

Two theories have been suggested to explain why primitive man first had recourse to internal remedies in the treatment of disease, the one being that it was accident, the other, imitation of the lower animals. Pliny's fabulous account of the origin of vivisection was that the hippopotamus, having become too fat and unwieldly through over-eating, thrust his nose into a sharp-pointed reed, and when he had drawn sufficient blood, he closed the wound with clay. Probably the first special treatment of disease was due to the Egyptians or Chaldeans; from them the Greeks obtained their knowledge, and Cheiron was the first to instruct his countrymen, among them Æsculapius, who is credited with being the originator of medicine as a distinct profession. Between the days of Æsculapius, who flourished in 1200 B.C., and those of Hippocrates, four hundred years later, medicine and myth are inextricably intermingled; the practice of the art seems to have been in the hands of a priesthood, who worshipped in temples devoted to Æsculapius as the god of physic. With the writings of Hippocrates a new era dawned, for they show a marvellous knowledge of injuries and disease, and contain methods of treatment founded on sound principles. As knowledge and civilisation advanced, although improvements in the art of medicine took place, quackery continued rampant. The credulity which the study of quackery discovers, almost approaches monomania or insanity. This credulity is explained by the fact that in all times there have been men and women of strong personalities and unlimited self-assertion who dominate their fellow-creatures and exercise a power for evil as well as good, and it is also explained by the natural tendency of a patient with a chronic illness to seek help from any source. Before dealing with quackery in the present time, some of its exponents in the past might be mentioned. There was Buley, for instance, in the days of Edward VI., who gave roasted rats as remedies to sick children; touching for the king's evil, which attained its height in the reign of Charles II.; the quack oculists of Queen Anne, who suffered from weak eyes, and was treated by Wm. Reade, a tailor, and Roger Grant, the cobbler and Anabaptist

preacher. Mesmer flourished in 1776, and a commission of the French Academy of Science was deputed by the king to investigate his claims. Among noted quacks of the past were Katterfelto, who wandered through the country with a caravan full of black cats, and was finally condemned as a vagabond by the Mayor of Shrewsbury; a Dr. Graham who sold an elixir of life to anyone who would pay him £1,000 for it, and conducted a Temple of Health in which Lady Hamilton, Lord Nelson's goddess, took part in musical performances. Again, there was the fat, ugly, tippling Mrs. Mapp, with her carriage and four, who was esteemed as a bone-setter, and known popularly as "Crazy Sally of Epsom." A very notorious quack was St. John Long, son of an Irish basket-maker, who acquired fame as a healer. His house in Harley Street was flocked to by the rank and fashion of the day, who were treated by inhaling some mixture through a tube. The street was often blocked by his patients' carriages; he was received into the best society; it is said that he made £13,400 in one year. He ended by being tried for manslaughter at the Old Bailey, but escaped with a fine of £250. Faith cures, and cures acting on the imagination, have thus flourished from very early times, and more recently a faith cure, under the name of Christian Science, has sprung up. In this we see history repeating itself. In ancient and more modern days so-called faith cures have been carried out by the aid of ceremonies and incantations, and the erection of temples to aid the imagination. According to what we read and hear, Christian Scientists are following in the same footsteps. If they aid in promoting temperance in alcohol and tobacco they will do good, but if they profess to cure disease by their methods, or to assert that there is no such thing as real pain, then we are justified in calling them quacks. How can quackery be checked? In the first place, the medical profession must not practise quackery themselves, for it is too true that it exists inside as well as outside of the profession. Then it is important to individualise in treatment so as to secure that patients may reap the greatest benefit, while careful and accurate diagnosis and prognosis will help to guard against disappointment. In this country there is no legislation against quackery. The Government receives £300,000 annually from the licences and stamp duties on the sale of patent medicines. Many patent medicines in no way comply with the law requiring that they must be genuine original inventions, and that a complete description of them must be filed at the Patent Office. In both France and Germany there is at present a great deal of agitation in favour of greater stringency in dealing with quackery, and stricter supervision of proprietary remedies. In conclusion, it is important to realise the responsibilities resting on those entering upon the practice of medicine, both in exercising the sympathetic faculty, and in cultivating friendly intercourse with patients of all classes.

The consumptive patients in Lambeth Infirmary have been in the habit of looking out of the windows of that institution overlooking Gilbert-road, but the residents loudly complaining that this habit created fear that contagion would be spread, the guardians have decided to remove the consumptives to other quarters.

SOME REMARKS ON A NEW FORM OF ADMINISTRATION OF FORMALDEHYDE.(a)

By H. W. O. SEIFERT, M.D.,
Professor at the University of Würzburg.

The pharmaceutical preparation known as formamint tablets represents the product of a two-fold combination of formaldehyde. They contain, with the addition of sugar and gum arabic, a proportion of ·01 formaldehyde, by weight, in 1 grm. of the total combination. Citric acid is added for purposes of palatability, while a few drops of pepsin-hydrochloric acid ensure the liberation of free formaldehyde during the solution of the tablets in the mouth. The tablets as put on the market are odourless and possess a pleasant refreshing taste.

Experimental investigations made with collections of streptococci, pneumococci, typhus, and diphtheria bacilli demonstrate that a solution of one tablet in 10 c.c. of water destroys their germs in from five to ten minutes. Culture tubes of bouillon, agar, or gelatine, to which this solution was added, proved sterile, so that no growth took place in them, while distinct and characteristic development of the bacilli took place in control tubes.

Experimental research on animals gave similar results.

The investigations of Rosenberg (1) prove beyond the possibility of objection, that formaldehyde is to be found free in the blood after internal administration. Further researches are required in order to determine in how far these formamint tablets are calculated to exert antibacterial and antitoxic actions in the body respectively, in the course of infectious diseases.

Formamint tablets are especially indicated in the treatment of infective diseases of the throat. They act as substitutes for gargles, and disinfect the area of disease locally, while they are also absorbed internally and influence the whole organism in general. The claim of formamint for therapeutic employment rests on its great bactericidal value. This value is of great importance in general practice, because of the various difficulties associated with efficient gargling, not only in regard to children, but also in the case of some adults. I have learnt to attach great significance to the worth of these tablets, because I used them extensively, in cases of follicular tonsilitis, during last winter and spring, and they have answered in excellent manner, more particularly with young children who were unable to gargle. These tablets stood me in very good stead in a case of ulcer of the posterior pharyngeal wall, the patient being three years only and incapable of gargling. There was great pain on swallowing and considerable fœtor emanated from the mouth. I ordered one half-tablet to be taken every two hours, and I found after the lapse of twenty-four hours that the pain on swallowing was greatly relieved, and the fœtor was almost gone. In six days the ulcer was healed.

Further evidence is required before an estimate can be made of the value of the formamint tablets in whooping cough, but I am fully satisfied of their efficacy in various forms of subacute and

(a) Reprinted from the "Pharmakologische und Therapeutische Rundschau." No. 14. 1905.
(b) Rosenberg: Therapie der Gegenwart. 4. 1905.

chronic pharyngitis. The irritability of the pharyngeal mucous membrane is diminished, and the phlegm is loosened.

When required the tablets may be dissolved in warm water of a temperature of 95° F. A solution of one tablet in about six drachms of water forms a disinfectant mouth wash, containing formaldehyde in the proportion of 1 in 20,000. It is stronger than a 5 per cent. solution of carbolic acid or a 1 in 1,000 solution of sublimate, and it is moreover absolutely unirritating.

Robert (*a*) records a case of a striking cure in fœtid bronchitis, under the prolonged use of these tablets.

They are splendidly adapted for use by school children as a prophylactic against infectious disease, especially during the prevalence of an epidemic. I am in the habit of prescribing one tablet for children as soon as they return home from school.

It should be further stated that for the last few months our skin and syphilitic patients who are undergoing mercurial treatment have been given these tablets, both in their ordinary and double strength, in order to avoid stomatitis. The results have been quite satisfactory. When stomatitis from mercury is once established the tablets have no effect.

As a result of my clinical observations I am compelled to state that formamint tablets are a valuable acquisition to our pharmacopœia, more especially in the treatment of infective inflammations of the mucous membranes of the mouth and pharynx.

CONCUSSION OF THE BRAIN (SO-CALLED) AND ITS TREATMENT.*

By W. THELWALL THOMAS, F.R.C.S.,

Assistant Surgeon, Royal Infirmary; Assistant Lecturer on Surgery, University of Liverpool.

SYNOPSIS.—*Peculiarities of the cerebral circulation. Simple concussion is either* (a) *altered equilibrium of fluid pressure in the cranium, or* (b) *shock. Continued unconsciousness denotes cerebral contusion or laceration, and its possible complications—encephalitis, arachnitis, &c. Prognosis: Treatment as for shock. Symptoms often prolonged by the use of ice. Brain contusion or laceration best treated by quietness, rest, sedatives; after-effects by iodides and free nourishment.*

PHYSIOLOGICAL research during the last decade has made it necessary for us to reconsider the question of concussion of the brain.

During life the cranial cavity is almost entirely filled by brain matter and blood, the amount of cerebrospinal fluid being so small as to be a negligible quantity, merely serving to moisten the surface of the brain and form small collections in a few places. If, from any cause, an excess of cerebrospinal fluid is secreted, absorption takes place once its pressure exceeds the cerebral venous pressure—equilibrium being quickly restored by absorption into the cerebral veins.

There is no evidence of the existence of vasomotor nerves or of any vasomotor mechanism in connection with the cerebral vessels, so that the circulation of blood within the cranial cavity passively follows the changes in the general circulation; in other words, the splanchnic vasomotor mechanism controls the cerebral circulation indirectly through the general circulation. Active spasm of the cerebral arteries or arterioles has never yet been demonstrated experimentally, and must be assumed not to exist.*

The ready absorption of cerebrospinal fluid by the veins makes the cerebral venous pressure of far greater moment than the arterial; obstruction to the venous return in heart disease or pulmonary affections readily affects the equilibrium of fluid pressure in the brain, and, as we know, often causes cerebral symptoms.

Gravity will have a marked effect on the cerebral arterial pressure if by any means the splanchnic vasomotor mechanism is in abeyance; thus, in chloroform anæsthesia, or shock, any sudden change of the posture of the patient to anything approaching the vertical, produces cerebral anæmia, and the result can be described as syncope, shock, or concussion. Brain matter in itself is incompressible; it thus follows that any compressing force acting within the unopened cranium, *e.g.* hæmorrhage or tumour, must act by displacing (1) cerebrospinal fluid, (2) venous blood, (3) arterial blood, and finally driving the medulla downwards into the foramen magnum like a cork into the apex of a funnel, and by producing marked anæmia leads to (1) failure of the respiratory centre, and (2) failure of the cardiac and general vasomotor centre—of course, quickly ending in death. Death from this compression (in an unopened cranium) may be delayed by providing an opening in the cranial vault sufficiently large to relieve pressure. This fact is realised when we remove areas of the skull to relieve the patient from the effects of cerebral tumour; in hæmorrhage the operation has, unfortunately, only a small range of usefulness, and that almost limited to extra-dural extravasation, where the source of the bleeding can be dealt with. To act on the cerebral arterial pressure it is, as I have already stated, necessary to do so through the splanchnic vasomotor mechanism; physiologists have failed to produce any direct effect on cerebral arteries or arterioles by application of cold or any other means to the exterior of the head.

This broad fact has always been empirically acted upon in former days by bleeding and free purgation, and so impressed is this on the medical mind, early in its development, that the medical student is always prepared to place a few drops of croton oil on the tongue of the hemiplegic, while at the same time he advocates perfect rest and quietness, I suppose, until the medicament acts, when the unfortunate patient is sure to be well shaken during the efforts of the nurse to clean up.

By the term "simple concussion," is meant that slight degree of dizziness, staggering, and mental obfuscation that occurs on slight injury to the cranial mass, directly or indirectly applied; it is so momentary that we rarely see it in a patient unless present when it is produced. At one period or another, in school days or subsequently, most of us have experienced it. So quickly are all the slight disturbances over, and so complete the recovery, that it can hardly mean more than a temporary disturbance of pressure equilibrium in the brain and semi-circular canals. Without knowledge of the causative circumstances, it cannot be distinguished from slight syncope or shock. The treatment is simple; rest in the horizontal position soon restoring the cerebral functions.

Squeeze a man's thumb in a vice, hit him in the scrotum with a cricket ball, strike him in the abdomen with the fist, let the uninitiated look on at a surgical operation, or pick up a man who in falling strikes his head against the curbstone, and you will find them all suffering from the same symptoms which I quote from my article on Shock in *Encyclopædia Medica*:—

"He staggers towards a seat or falls, the lips become livid or bloodless, the skin pale, and there may even be partial loss of consciousness. Respiration may be temporarily suspended, then reappear in shallow gasps, wanting the relief of sighs. The heart beats feebly and frequently, and the pulse of course likewise. Surface temperature is much reduced, although the rectal temperature may only be down a degree or two. A cold perspiration bespangles the brow, and the individual exists by reason of the automatic action of his essential centres, the cardiac and respiratory—his

(*a*) Robert: Deutsche Militärärztl. Zeitschr. 1905. No. 5.

* A Clinical Demonstration given in the Out-patient Clinique of the Liverpool Royal Infirmary.

irreducible minimum. The patient loses heat in ordinary surroundings, and the feeble circulation means feeble oxidation of the tissues and deficient interchange of oxygen and carbonic acid. Continued exposure, particularly if the trauma be severe or continuous, will bring about a fatal result. All these symptoms are brought about by—

"1. Reflex paralysis acting on the heart through the medulla, leading to (*a*) slowing or even arrest of the heart's action, and (*b*) on the respiratory apparatus similarly.

"2. Interference with the action of the vasomotor apparatus, leading to a great fall in blood pressure; inspissation of the blood; interference with the interchange of O and CO_2 in the tissues, and loss of animal heat.

"3. Molecular change in the nerve cells bringing about fatigue and exhaustion.

"4. Hæmorrhage, if present, markedly influences all the above changes."

Direct injury to exposed brain in surgical operations, even removal of portions, or exploration, with necessary damage, does not produce any marked shock; neither does chiselling areæ of bone from the skull, even extensive resections, using a V chisel and heavy mallet with great force, cause "concussion"; provided the patient is fully anæsthetised, and no great hæmorrhage or prolongation of chloroform anæsthesia has been necessary. Why the difference in the effects with or without anæsthesia? What has the chloroform done? Simply destroyed the vasomotor reflex. Surely $CHCl_3$ ought to make no difference if direct concussion to brain is the cause of the symptoms usually described as "concussion." The injuries to other parts of the body previously mentioned, likewise under anæsthesia, do not produce shock. One is forced to the conclusion that the terms "shock" and uncomplicated "concussion" are really the same in cause, effect, and pathology.

Deaths may occur from shock just as from the same condition produced by head injuries, and leave no naked-eye pathological lesions. The treatment of this condition is to be carried out on exactly the same lines as we prescribe for shock—rest, quietness, warmth, and liquid nourishment, together with diffusible stimulants, digitalis, strychnine, &c.

The quieter a patient is kept, and the freer from worrying busybodies and friends, the quicker the recovery; a general hospital ward is not the ideal place; a darkened room or isolation ward, well warmed; quiet nurses, the absence of all noises, and the patient will quickly recover. Put an ice-bag on a patient's head in this condition, and you can keep him depressed and in his automatic state for almost as long as you renew the ice; you are only depressing the general blood-pressure, and going a long way towards "cold storing" his scalp. It has been shown that cold to the head can have no direct effect on the cerebral circulation, and it is difficult to understand how ice-bags or Leiter's tubes have still remained the stock treatment; they rightly belong to the era when it was thought necessary to prevent reaction (recovery) to take place too suddenly, and to prevent the onset of the feared inflammation of the brain. It is difficult to realise the great general depression produced by cold applications to the head. Let anyone try the effect of keeping the head under a running tap of cold water; the feeling of burning which quickly follows the initial cold sensation soon ends in faintness, great depression, and shock.

If the unfortunate patient be unconscious when the ice is first applied, he can be kept from "coming to" by diligently renewing the cold application. I have seen a patient on whose head ice-bags had been most assiduously applied for three weeks (with the simple exception of three hours, when the supply gave out, and he tried to struggle back to consciousness) reduced to the condition of a hibernating animal. Pulse 56, respiration 12, temperature 96°, the pupils reacted only slightly to strong light. He could be slightly roused by shouting in his ear to a dull perception of his surroundings, but immediately relapsed. He could swallow fluids poured slowly into his pharynx; and whenever his brain realised that the urinary bladder required emptying, he made feeble attempts to get out of bed, and would micturate into a vessel placed in contact with the penis. Notwithstanding such evidences of the struggles of his sensorium against this freezing treatment, it was continued for the time mentioned.

Following a consultation, the ice-bags were removed and a counter-irritant applied to the nape of the neck. He recovered so quickly as to overpower his female nurses, escaped downstairs, and did a "sprint" down a country road in the dead of night, when the temperature was low, and he was clad only in invalid garments. Despite an attack of acute rheumatism and pneumonia, he made in the end a perfect recovery.

Another case of a young boy, who, when diving into shallow water, struck the bottom and became "concussed." He was diligently "frozen" for ten days, and was in exactly the same condition as the previous patient. The removal of the ice, followed by counter-irritant to the back of the head by liniment of iodine, quickly brought about reaction and recovery; he sat up in bed next day, asked for, and obtained, a mutton chop from his anxious and excited mother. Did time permit, other cases could be mentioned.

What I have endeavoured to maintain is that shock and ordinary concussion are one and the same thing, that the same treatment applies to each, and ice bags are not indicated.

Severe concussion or continued unconsciousness implies definite naked-eye pathological lesions of the brain or meninges, contusion of the surface of the brain, and hæmorrhages into the meninges, or laceration of brain substance. The symptoms are different from those of ordinary surgical shock. Should the contusion or laceration be very extensive, basal or bulbar in situation, death is speedy; rapidly increasing unconsciousness (without conscious interval), twitchings, convulsions, paralyses, and progressive coma with stertorous breathing, when every respiration seems to be the final one, or Cheyne Stokes breathing, terminates the life of the patient. The pulse becomes slow and full, then falls in volume; the pupils dilate, and do not react to light.

Hæmorrhages occasionally occur in special motor areæ and lead to localising diagnoses, but they are often multiple and confusing from an anatomical point of view, *e.g.*, paralysis of one arm, with paralysis of the leg of the opposite side. It is well, therefore, to hesitate before undertaking operation, unless the diagnosis be lateral extra-dural hæmorrhage, which has decided symptoms and signs when uncomplicated. Rapidly increasing coma with complicated paralysis generally indicates multiple hæmorrhages and lacerations, and is beyond the range of practical surgery.

Can we differentiate between contusion and laceration? When the initial severe shock is over, certain points of assistance in diagnosis have been noticed. When the cortex is irritated by the extravasation we have marked irritability, restlessness, and other sensory disturbances, together with a busy delirium, very similar to mild delirium tremens. Twitchings or slight pareses may be present, rarely marked paralysis. Temperature is not affected—certainly not elevated. In average cases the patient does not drift into coma, but remains in a very "bear-with-a-sore-head" condition, called cerebral irritation; the patient lies in a universally flexed condition, he will answer when called to loudly, but the answer may not be quite what is expected, and is often interlarded with language lacking in style, or even decency. He will swallow liquid food poured gently into the pharynx, but is often very obstinate.

The treatment of this condition needs good nursing, firmness, tactfulness, and, indeed, muscular strength, for the sufferer frequently tries to get out of bed. Some form of restraint may be necessary, and sedatives are absolutely essential.

Ice-bags applied to the head are of service here, but

it should be clearly understood that their action is that of a general depressant, and not any fanciful therapeutic idea that they act directly on the cerebral circulation.

Chemical sedatives are preferable; very small doses of morphine (gr. $\frac{1}{4}$), repeated if necessary; in some cases hyoscine hydrobromate (gr. $\frac{1}{100}$) appears to be more useful; in one case where respiratory failure was threatening, hyoscine, atropine, and morphia, in suitable doses, were of marked benefit.

Chloral hydrate, in an initial dose of 20 grains, followed by 10 grains hourly, until its effect is produced, has been useful (this can be administered per rectum). If one drug loses its effect, another should be tried. Bromides seem powerless, and I now never prescribe them. It is important that the sensorium be calmed, and kept so; this is our sheet-anchor.

A chart, recording pulse, respiration, and temperature, should be taken, hourly if possible; and if a normal ratio between these three items be maintained, prognosis is favourable, provided the patient can be coaxed or forced to take sufficient nourishment. The cases last sometimes for weeks. The bowels must be attended to, but there is no need for drastic purgation.

Nourishment is of paramount importance from the earliest stage, to provide for the bodily wear and tear; for if the patient is very restless, marked emaciation soon shows itself. He must be cajoled by efficient nurses to take nourishment regularly. There soon comes a time when restlessness subsides and the sedatives are required less frequently. This is the opportunity, with return of consciousness, for dieting, and for administering *iodides*, which have a marked action in clearing up the muddy state of the patient's intellect, and preventing, I am sure, the after-effects so frequently mentioned in connection with concussion—headache, irritability, alteration of disposition, loss of memory, &c. The iodides probably act by hurrying the absorption of exudations. It is well to continue their administration for some time after the patient appears to be well.

I well remember a patient with severe headache and depression, who had been dosed with bromides without any good result, on being treated with iodides internally, remark that his pain went soon after beginning the "new medicine," and he used the expression that the medicine "wiped the slate clean."

Time will not permit of a lengthy consideration of cerebral laceration. Should this be extensive, the temperature rises rapidly (while the pulse and respiration remain fairly normal), and may become very high just before death.

Loss of bladder and rectum control, with rapidly increasing coma, is rare in contusion, but might be considered characteristic of laceration. A sudden rise of temperature is always suggestive of meningitis.

Time will not permit of a lengthy consideration of cerebral laceration in all its degrees and possible complications.

In conclusion: . it is a useful addition to treatment in all severe cases of head injury to clip the hair very short, or even to shave the head. This enables a thorough examination of the scalp, and renders the patient more comfortable.

It was not my intention to weary you with details of many cases, but to bring to your notice the deductions drawn from them.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

SYPHILITIC DISEASE OF THE KNEE WITH CEREBRAL SYMPTOMS.

By PEYTON BEALE, F.R.C.S.

AMONGST the out-patients was a woman, æt. about 35, complaining of pain in the right knee which was especially severe at night. Her account was that the knee had been gradually swelling for the last fortnight with increasing pain, but she knew of nothing to account for the onset of the symptoms. The pain was worse after exertion. On examination, the right knee was swollen, there was no heat, movements were perfect and practically painless. The swelling was obviously in no way connected with the skin, and it certainly did not involve the periosteum or the bone. From the fact that the normal depressions around the patella were replaced by swellings, and that fluctuation was easily obtained in the joint, the patella floating, it was quite clear that the swelling of the knee was partly caused by synovitis leading to an effusion of fluid into the joint. It was also obvious that there was considerable thickening of the synovial membrane. No other joints were or had been affected. On further examination, several scars were seen below and to the inner side of the right patella, but no others were found in any part of the body. All attempts to elucidate any previous history of syphilis were quite unavailing, but Mr. Beale said that in spite of this he should at once assume that the scars were the result of gummata, and that the synovitis was probably also syphilitic. The patient was given mercurial ointment to rub into the skin over the knee, and 2 grs. of hydrarg. c. creta internally. Under this treatment the pain in the knee improved and the swelling began to subside. In a fortnight's time the patient complained of some weakness in her left arm and leg; she also had slight left facial paralysis. She was now given further mercurial inunctions in the form of mercurial ointment to be rubbed into the groins and axillæ on alternate days. The paresis became more marked during the next few days, but disappeared within a fortnight. Mr. Beale remarked that this case was in all probability one of gummatous infiltration of the synovial membrane, a condition not commonly met with. In the secondary stage a diffuse synovitis affecting joints successively was fairly common. As regards the paresis, he had little doubt that this was caused by some thrombosis really due to syphilitic endarteritis affecting some of the cerebral vessels, for its onset occurred at night during rest and was at first very slight in extent. He had often observed that these symptoms of thombosis were prone to occur amongst the earliest of tertiary symptoms, but the interesting fact was, he thought, that they commonly occurred in syphilitic cases in which the primary sore had been very small, and in which the secondary symptoms had been very slight indeed. It was sometimes stated that this was due to the fact that the primary sore had been altogether overlooked, so had escaped treatment; but he had come across several cases in which this cerebral thrombosis, as evidenced by slight one-sided paresis, often associated with headache, had appeared as the first tertiary symptom within eighteen months of the primary sore, which, although small and insignificant, had, nevertheless, been recognised and energetically and properly treated.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

PERFORATED DUODENAL ULCER, SUTURE, RECOVERY.—Mr. WILLMOTT EVANS operated on a man, æt. 45, who had been admitted two hours previously complaining of severe abdominal pain. The patient stated that at 10.30 in the morning he had been seized with a slight pain in the upper part of the abdomen a little to the right of the middle line, but the pain had not been sufficient to prevent his continuing his work; at 5.30, however, on the same day, the pain returned and became so severe that he had to go home. He was brought to the hospital some four hours later. At that time he complained of very severe pain in the site mentioned, sufficient to prevent him standing. On examination by Mr. Evans, the abdomen was found

extremely rigid, the right rectus being even more rigid than the left; percussion gave no abnormal signs except that the liver dulness seemed slightly diminished, the pulse was small, frequent and readily compressible, the patient was much collapsed. No history could be obtained of hæmatemesis or melæna. The diagnosis was made of perforation of some portion of the alimentary tract and a perforated duodenal ulcer was considered probable. Some delay was caused by the refusal of the patient to submit to operation, but at midnight, consent having been obtained, the abdomen was opened by a three-inch incision above the umbilicus in the middle line. The stomach was examined and found intact, but at the upper and back part of the duodenum, immediately external to the pylorus, was found a perforation about one-eighth of an inch in diameter; a little extravasated material was seen round the opening. Great difficulty was experienced in getting at the perforation, for many old adhesions existed fastening down this portion of the duodenum, and it was found necessary to make a horizontal incision from the middle of the first one. The opening in the duodenum was brought together by four or five fine silk Lembert's sutures, which turned in the edges of the perforation. Mr. Evans also thought it advisable to fasten over the area a small omental graft. The abdominal cavity was then flushed with large quantities of saline solution at a temperature of 105°. The wound was then closed, some little difficulty being experienced in getting the edges to meet; the patient was then returned to bed. Mr. Evans said that the diagnosis of this case was a probable duodenal ulcer which had perforated, the site of the pain and the sex of the patient being a little against a perforation of a gastric ulcer. In such cases as this it was unnecessary, he thought, to attempt to make a certain diagnosis, inasmuch as the abdomen must be opened. The only points of importance in the operation, he said, were the flushing and the absence of drainage. Some surgeons, he pointed out, had spoken against flushing the abdominal cavity with saline solution, as they maintained that it acted as a depressant. He thought that might well be the case if the saline solution were introduced at too low a temperature. It should not be forgotten that the normal temperature of the interior of the abdomen was 100° F., and therefore any fluid introduced must be at least as hot as that, but it was better, he considered, to have the saline solution at least two or three degrees higher, as its temperature would fall a little in passing from the irrigator to the abdominal cavity, and, moreover, some of the abdominal contents would become slightly chilled by the operation itself; he therefore thought it advisable that the water in irrigating should be between 105° and 106°. Saline solutions used to flush the abdomen had, he remarked, several functions. In the first place they diluted any toxins or micro-organisms which had already been introduced into the abdomen; in the second place, they, by their presence, tended to prevent the formation of adhesions; and in the third place, they provided a large quantity of normal saline solution, which could be absorbed readily by the lymphatics and capillaries, and so serve to keep up the blood-pressure. With regard to the other point of importance in the operation, *i.e.*, the absence of drainage, many surgeons, Mr. Evans said, considered it necessary to place drainage tubes in each flank and above the pubes in order to assist in carrying off some of the extravasated materials. There could be no doubt that openings such as those might assist greatly in the washing-out of the abdominal cavity, but, on the other hand, every such opening formed a fresh channel through which micro-organisms could enter the abdominal cavity; he therefore did not think it advisable to make drainage openings except in cases where the amount of extravasated material was especially great.

The patient progressed satisfactorily; sips of hot water were allowed after the first twelve hours, and liquid food was given at the end of the week; meanwhile the patient was fed by nutrient enemata. A little sloughing of a portion of the subcutaneous tissue at the edges of the incision occurred and delayed somewhat the healing of the cutaneous wound. In all other respects the progress of recovery was uneventful.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug. 5th, 1906.

At the Surgical Congress, Dr. Bier, of Bonn, gave some of the results of his

Treatment of Inflammation by Artificial Hyperæmia (Bier's Stasis Hyperæmia).

He had, up to the present, treated 1,500 acute inflammation, 1,100 of which were treated by "suction" treatment, mostly slight cases. In 236 cases the stasis bandages were used; the other cases belonged to the earlier days of the treatment. Of the severer cases 25 were phlegmons of the sheaths of tendons, in which pus was present, 18 recovered without necrosis, 7 with partial necrosis. Almost perfect movement was retained in the first group of cases; amongst these were six severe phlegmons of the fingers; perfect function remained in four cases. In the cases recovered with necrosis, it was ascertained that the necrosis was present before the commencement of the treatment. It was true that early phlegmons had been successfully treated before, but generally without retaining good function, whilst in the cases treated with artificial hyperæmia the function was perfect in 50 per cent. Of 22 cases of acute osteomyelitis, 11 recovered with and 10 without necrosis (one died of pyæmia), but they were mild cases affecting small bones, and these results had been already obtained with free opening. Better results were, however, undoubtedly to be obtained when the stasis bandage was applied at the onset of the disease. More recently the results obtained in children at the commencement of the disease were quite satisfactory.

As regarded joints the traumatic suppurating joints were of special importance; of these the severest cases had recovered with unimpaired movement. 28 cases of suppuration of the ear were treated in this way, 27 of them complicated by mastoiditis; of 17 acute cases, *i.e.*, such as had not lasted more than two months, 16 recovered after slight incision in the mastoid process, with good hearing power, as was proved on examination by an ear surgeon. This was a warning to treat cases early. It was to be remarked, however, that stasis hyperæmia was not so simple a procedure; practice, care and conscientiousness were requisite.

As regarded less favourable results, he saw only partially good results in erysipelas, and this agreed with the observations of other surgeons. As regarded streptococcal diseases, he had but little experience, as they were very rare in Bonn. The view of Lexer that artificial hyperæmia acted well only in mild cases, uncertainly in moderate ones, and not at all in serious cases was not in accordance with many experiences, and just as little that the latter should be treated with extensive incisions. The joint should not be firmly fixed, as movement suffered by fixation; early active movement in a warm bath was recommended. Pain from the bandage was not a contra-indication; it resulted generally from imperfect technique. The most difficult part of the treatment was the determination of the indication; it required further working out.

He observed that at first he was called a mystic and a vitalist, to-day he was called a mechanic and an empiric; he would in the future endeavour to proceed scientifically.

A discussion on the subject was taken part in by a large number of surgeons. Indeed, if one may judge of the interest and importance of a subject by the number of people anxious to take part in a discussion of it, Bier's hyperæmia was the most interesting topic before the meeting.

Herr Habs, Magdeburg, discussed the contra-indications for it; these were erysipelas, venous thrombosis and the gangrene of diabetes.

Herrn Körte and Kruse, Berlin, had seen good results, but the latter not so in three severe cases of osteomyelitis. Herr Sietz, Hamburg, had treated 250 cases in this way. In most cases a good result was observed as regarded pain, fever and retention of function. Herr Stich, Breslau, reported "right favourable" results.

Herr Danielsen said that in Küttner's Klinik, Marburg, the treatment had been employed in 260 cases, and it had only failed in six owing to defective technique. After some days the treatment should be discontinued if no good result was obtained, and no large incisions should be made. He held the hyperæmic method to be the greatest surgical acquirement of recent times.

Herr Bardenhauer, Cöln, had practised the method for two years, at first with great reluctance, then through the agency of his assistants he became a fervid adherent to the system. At first he failed to retain movement in joints, but he was now successful. We should make only very small incisions as recommended by Bier. In this way seven cases of osteomyelitis recovered with power of movement in the joints, the same with bad phlegmons and furuncles. Here was used the suction treatment.

Herr Heidenhain had also had good results. He gave the two following rules: in the intervals between the bandagings the œdema set up should be allowed to subside and where pus was present small incisions should be made. The hyperæmia had an unconditionally anti-inflammatory action; the pus cocci died off. It had also a prophylactic action in amputations. Cicatrices after the hyperæmic process were uncommonly soft and were not distinguishable from the surrounding tissues.

Herr Perthes, Leipzig, said that the favourable action of hyperæmia could not be denied.

Herr Hoffmann, Carlsruhe, said the effect was very good in soiled wounds and compound fractures; the vessels were dilated and the leucocytosis diminished, but the chief thing was that the secretions were conducted outside.

Herr Kuster, Marburg, said that stasis hyperæmia was the most important advance in clinical surgery since Lister. It came in where aseptic treatment failed. Many other surgeons took part in the discussion, amongst whom were Ranzi, Vienna; Thöle, Dantzic; Haasler, Halle; Blumberg, Berlin, and others. All spoke favourably of the treatment. Lexer, of Konigsberg, the least so. The last-named gentleman seemed to take pleasure rather in dwelling on what it could not do than in contemplating its undeniably good effects when intelligently employed.

AUSTRIA.

Vienna, Aug. 5th, 1906.

A RETROSPECT OF CARCINOMA OPERATIONS.

WERTHEIM interested the Gesellschaft with a history of his operation in carcinoma of the uterus. He quoted 60 cases operated on five years ago, 60 operated on four years ago, and over that number for three years. Gynæcologists would admit that the first 60 were the most important, but it was interesting to note how different operations acted on the recurrence of the disease. In the distended vaginal operation it would appear that recurrence hardly ever takes place before that period (fifth year) after operating. For those over five years he had 60 per cent. entirely free from any symptom of recurrence, which he considered an extraordinarily favourable result when compared with previous operations. The statistics of all such operations per vagina, prior to Schauta, were always given as 20 or 25 per cent., and the very best recorded are 30 per cent. With this new vaginal operation every second woman operated on escapes for upwards of five years—hitherto only one in seven—even with extirpation of the uterus. According to Wertheim's last 90 cases, only 15 per cent. died two years after the operation and 9 per cent. after reaching one year.

Wertheim attributes this happy result to the present methods of operating for cancer in the neck of the uterus.

Extirpation by laparotomy keeps the patient far too long under the influence of the anæsthetic. Shorten the period of operating, and you extend the term of life. Make every preparation for expedition in clearing out the cancerous growth. Lumbar anæsthesia provides another excellent method of operating.

Wertheim has done 15 cases recently by the subcutaneous injections into the lumbar region with the best results; only one proved refractory, and inhalation had to be resorted to. He is now confident that distended vaginal operations for cancer in the neck of the uterus has obtained an abiding place in gynæcological surgery. He reminded his audience that five years is all that they can reasonably expect under very favourable circumstances.

Bürger said Schauta had introduced the vaginal method five years ago, and obtained very good results then which are now confirmed by Wertheim. It should be understood that the vaginal method before that time is not the vaginal method of to-day. Wider incisions are now made into the parametrium preparatory for the excision of the morbid growth. The glands are not extirpated in this operation, as it is very problematical whether they hasten or retard recurrence of the disease. Schauta's results were 50 per cent., while Wertheim tells us that his are 60 per cent. after five years, or, in other words, six times better than the old vaginal operation in vogue when Schauta commenced operating.

GLAND INFECTION IN CARCINOMA.

Latzko exhibited a number of preparations taken from the glands of patients suffering from uterim and vulvar carcinoma, and compared them with the glands taken from other parts of the body, such as the mamma, &c., where extirpation of cancer and glands were performed. The radical operation of cancer glands and vessels has not given the results expected. There is no improvement in the time limit. There is still a good deal of confusion about the iliac hypogastric and internal inguinal glands being in close connection with the uterus. Their presence does not appear to increase the danger of recurrence.

PSEUDO-BULBAR PARALYSIS.

Hoesslin records a case of diagnosed bulbar paralysis, which revealed at the post-mortem two apoplectic centres at the lower portion of the second and third convolution of the frontal lobe. The bulbus was examined microscopically and found perfectly entire.

MULTIPLE SCLEROSIS.

Selling records a case of multiple sclerosis, where the "main de prédicateur" of Charcot was the dominant symptom. The three outside fingers are bent, while the index and thumb are extended. The motor or anterior horn of the spine is admittedly injured, but this symptom was usually accepted in pachymeningitis cervicalis hypertrophica or syringo myelia as pathognomonic, but not in multiple sclerosis. Selling's history and pathological sections put it beyond dispute that the symptom of "main de predicateur" is not confined to pachymeningitis or syringo myelia.

THE Military Academy of Medicine of St. Petersburg has decided to admit no more Jewish students.

HUNGARY.

Budapest, Aug. 5th, 1906.

At the recent meeting of the Royal Hungarian Medical Society, Dr. Schmidt read a paper on

AUSCULTATORY PERCUSSION.

He said that lately a number of articles have appeared in the world's medical press, which tend to throw discredit upon auscultatory percussion as applied to the heart. Entirely faulty boundaries are obtained, it is assumed, and the varying tension of the skin will permit the percussion of heart-shaped figures even over other parts of the thorax. He asserted that this is due to faulty technique. He has made hundreds of examinations, and has controlled the accuracy of the method by means of the X-rays. Considerable experience is required, as skin-tension must be carefully avoided; the stroking should be practised with a fine brush, or, better still, with a small drum, which is rolled over the chest, and to which a brush is attached. Various drugs, warm baths, &c., undoubtedly cause a change in the cardiac contours.

In the *Orovsok Lapja*, Dr. Preisich published an able article on

ALBUMINURIA OF PUBERTY.

It is not generally known that a large percentage of boys from fourteen to eighteen years of age suffer from albuminuria without having nephritis. The author had the rare opportunity to examine repeatedly over 500 young employees of a large factory, and discovered albumin in no less than 19 per cent. In most cases, only traces could be detected, though in a few the amount exceeded 1 per mill. The greater part of the albumin seemed to consist of globulin as in acute nephritis, including the presence of wide meshes in the filtering apparatus of the kidney. The cause of the albuminuria, which generally had an intermittent character and was orthostatic in type, was to be found in an impoverished condition of the blood, together with a mild degree of cardiac insufficiency and tendency to stasis, such as is liable to occur during puberty, where the rapid growth of the body is out of proportion to the functional powers of the internal organs. In accord with this, dilatation of the heart, tension of the arteries, and accentuation of the second aortic sound were frequently noted. The condition is readily outgrown, since it was not found in any of the men above twenty-five years old of the same factory. It is often difficult to distinguish from chronic interstitial nephritis, but the slightest amount of albumin, the rare occurrence of casts of hyaline character and the distinct intermittent type speak against the latter. Moderate cardiac changes are of no value, as they occur in both.

Dr. Landoer has studied the congealing point of the blood-serum under various conditions, in order to determine to what extent this may be looked on as index of renal function. Unfortunately his results tend to minimise the practical importance of cryoscopy. It appears that food has little influence; thus with a strict milk diet normal figures were obtained, though the serum was considerably poorer in nitrogen than before. This nitrogen loss depended upon a deficiency of albumin; since albumin, however, consists of very large molecules, no variations in the freezing-point below 0.58 C. seems to point to a retention of excrementitious products, but normal figures indicate renal sufficiency only if the serum is not poorer in nitrogenous substances. Even in uræmia and advanced nephritis, cryoscopy may give no clue as to the condition of the kidneys, since a dilution of serum occurs which compensates for any change. This fact will limit the usefulness of cryoscopy in surgery considerably, unless accompanied by a chemical examination of the serum. Occasionally the latter will also yield normal results in nephritis, but here the compensation is perfect. The influence of fever, as in typhoid, pneumonia, &c., is not constant, as the pressure may be normal, increased or diminished without any relation to the nature of the disease. In diabetes, the freezing-point was generally found subnormal, owing to the presence of glucose, acetone and diacetic acid in the serum. In pernicious anæmia, the serum congealed at a somewhat higher temperature than normal, owing to larger amount of water present.

LETTERS TO THE EDITOR.

TRANSMISSION OF SYPHILIS

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whatever in my knowledge of syphilis I account most exact and valuable I owe to the teachings of Mr. Jonathan Hutchinson; and the experience of many years has proved to my satisfaction the correctness in the main of his views. On numerous occasions in former years you have allowed me to take part in discussion of the subject in your columns. The last of these occasions was in March 1897. I have always contended that the injurious effects of syphilis have been often greatly exaggerated. It would be probably going too far to say that syphilis in men of good constitution leading temperate, healthy lives is rarely a very harmful disease even when not energetically treated; but it is not too much to affirm that the great majority of such cases after systematic treatment by a properly directed course of mercury extending over a sufficiently prolonged period, may be considered cured, so rare is the appearance of any subsequent serious symptoms. It is almost solely in patients of bad constitution or intemperate, dissipated habits that the disease runs a malignant course. I am satisfied, however, that general paralysis and locomotor ataxy are much more common sequels of cases which have not undergone thorough mercurial treatment than of those in which this treatment has been persevered in to the satisfaction of a vigilant surgeon. With regard to the transmission of syphilis, I believe that a syphilitic father whether he has been thoroughly treated or not, seldom begets tainted offspring after disappearance of the secondary symptoms, say after lapse of two years from the date of primary infection. Of this fact I could bring forward many cases in proof. With efficient mercurial treatment during the first two years I am convinced that the danger even immediately afterwards of producing infected children is very small, and that after the lapse of another two years even in cases where symptoms persist and are constantly treated by mercury and iodide of potasium, the danger of transmitting the disease can no longer be said to exist.

I have examined many thousands of children in hospital practice in my time, and the number presenting unequivocal signs of syphilis even among the progeny of undoubtedly infected parents has been very small. "Scrofula" tuberculosis and rickets are often mistaken for syphilis, and among minor signs "honeycombed" teeth—teeth with rough, imperfect enamel or spinous crowns—are often mistaken for the typical teeth originally described by Mr. Hutchinson. These latter teeth when present form an unequivocal sign of syphilis; but they are by no means found invariably even in children unquestionably the subjects of inherited syphilis. Typical syphilite teeth are very rare; they are not discoverable in more than five per cent. of tainted children. Syphilis is responsible for so much unhappiness that it will be well when some portion can be reduced through the general appreciation and acceptation of Mr. Hutchinson's views so admirably set forth in the clinical lecture published in your issue of August 1st. If this were the case a less pessimistic prognosis would more often be given to young men contemplating matrimony. Many a life has been spoilt for lack of authoritative assurance that marriage after syphilis need not necessarily involve any danger worth considering to either wife or progeny, much less to a third generation.

I am, Sir, yours truly,

AN AVERAGE PRACTITIONER.

August 2nd, 1906.

THE MYSTERIES OF THE CANNED MEAT TRADE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The case heard at Lambeth Police Court on August 3rd forms perhaps the most revolting story as yet publicly unfolded of the mysteries of the canned meat trade. The newspaper reports do not make it quite clear what were the quantities of suspected meat from the same source reaching the market weekly, but as one dealer deposed that he was receiving fifty-two tons a year, the amount disposed of may have been enormous. The seizure in the present case amounted to about 106 pounds. Dr. Bousfield stated that the sample of "beef or brawn (?)" which he examined contained an abscess cavity filled with pus. The meat had been dyed with aniline dye. The consignments of meat came from Wolverhampton, not Chicago, but the efforts to trace the man who deliberately prepared and disguised the diseased carcase, had failed. The holders of the canned stock were able to satisfy the magistrate as to their honesty and *bona fides*, and beyond the infliction of a nominal penalty for carelessness upon one of them, the prosecution broke down. Under the public Health Act, proceedings can be taken only against a dealer in whose hands the bad food is found and the firm from whom he bought it. In this case neither of the parties summoned were primarily responsible, nor was guilty knowledge proved against them. The case serves to show once more how defective are our sanitary laws, and how they serve in many cases merely to give an entirely false sense of security to the public. The public cannot imagine that elaborate codes of laws may appear on the statute-book devised to protect their interests, whilst no adequate machinery has been provided to enforce them. Laws against the sale of unwholesome and adulterated food are provided, therefore articles of food are pure; so reasons the average householder, and this confidence provides the opportunity for the fraudulent tradesman. It would be satisfactory if there appeared any prospect of legislation which should effectually put a check upon practices so injurious to the health of the nation, but no such prospect is in sight.

I am, Sir, yours truly,

VIGILANS.

MOTOR-CARS AND DUST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a sufferer from motor dust (and who is not), and as a member of the same profession as Dr. Gilchrist, I beg to join issue with him in his championship of motors. I happened to be staying at Matlock last week when reading his letter in your issue of August 1st, and the dust raised by passing motors was so terrible that I preferred to change my quarters rather than spoil my holiday by breathing the dust-laden atmosphere created by them. Your correspondent maintains that "it is the horse pounding with his iron hoof, and the metal wheel of the vehicle he draws that are responsible for the conditions you justly condemn." If this be so, how is it the dust nuisance has become so intolerable the last year or two, that special legislation has been found necessary to control its origin, and that people living in main roads most traversed by motor-cars are giving up their houses and removing to side streets not patronised by the modern Jehu?

Dr. Gilchrist writes from Nice. I, too, know the Riviera well, and my opinion when last there, two years ago, was that Nice and other beautiful health resorts along the Mediterranean, were being utterly ruined by the modern curse of civilisation—"motor dust."

I am, Sir, yours truly,

J. WILSON.

August 6th, 1906.

MR. CHARLES LEEDHAM-GREEN, M.B., F.R.C.S., was appointed honorary surgeon to the Queen's Hospital Birmingham, in place of Mr. Bennett May, resigned.

OBITUARY.

PAUL BROUARDEL,

PROFESSOR OF FORENSIC MEDICINE AT THE UNIVERSITY OF PARIS.

BY the death of Professor Paul Brouardel on Monday, July 23, the Faculty of Medicine of Paris loses one of its best known members. Born at St. Quentin in 1837 he took his degree at the Paris Faculty in 1875. He was appointed professor in 1879, and attained that much coveted distinction of election as Member of the Academy of Medicine in 1880, followed in 1892, by membership of the Academy of Sciences.

The Professor was a pupil of Tardieu, whom he succeeded after a comparatively short "stage." His name is associated principally, though not exclusively, with legal medicine and public hygiene. His reports as medical expert delegated by the tribunals attracted attention by the care, skill and method with which they were put together, and directly he was appointed lecturer on forensic medicine, left vacant by the death of Tardieu, he at once inaugurated a series of practical lectures at the Morgue, which were highly appreciated by many generations of students and practitioners in spite of the exiguity of the accommodation and the insalubrity of that famous, if lugubrious, building.

He was elected president of the Comité Consultatif d'Hygiene in 1884, and became Dean of the Faculty of Medicine in 1886, in addition to which he filled many official posts, so that he led a very busy life. In spite of this he devoted much time and thought to medical deontology *alias* medical ethics, and his works and contributions on the subject are known world wide. The English conception of professional secrecy is so fundamentally different from the French that the author's utterances found little echo on this side of the Channel.

He was constrained to relinquish work last winter in consequence of chronic laryngitis, and when the disabling tendency of the disease became manifest he went to live in the south of France. He leaves a widow without children.

Dr. Brouardel's great merit in the eyes of posterity will be that he was from the first one of the few to grasp the pre-eminent importance of hygiene as a factor in the public weal. He unhesitatingly threw his very great influence into the scale and did much to educate the public, and even the profession, in the principles of personal and national hygiene.

The funeral took place amid a great gathering of colleagues, friends and admirers.

DR. ANDREW D. DUCAT.

MUCH regret is felt at the death of Dr. Andrew D. Ducat, which occurred, in his 68th year, at Grosvenor-road, Canonbury. A native of Arbroath, he graduated M.D. at Edinburgh in 1863, and held for thirty-nine years the position of medical officer for the Highbury district. He was an elder of the Park Church (Presbyterian), Grosvenor-road, and an honorary president of the London Forfarshire Association.

EDWARD FRANCIS WILLOUGHBY, M.D., D.P.H.

WE regret to announce the death of Dr. Edward Francis Willoughby, honorary medical officer to the Mansion House Council on the Dwellings of the Poor, who passed away on July 29th at his residence, Bratton Lodge, Finsbury-park, after only a week's illness, in his sixty-seventh year. Educated at University College, London, he took the M.B. degree with honours at London University in 1869, the diploma in public health both at London and Cambridge in 1881, and proceeded to the M.D. degree at London University in 1889. Dr. Willoughby was a well-known contributor to medical literature, and published many works on hygiene. He also edited "Chaucer's Prologue to the Canterbury Tales."

EDWARD MACKEY, M.D.Lond., M.R.C.P.

Dr. Edward Mackey, of Hove, senior physician to the Sussex County Hospital, died on July 29th in London, after a short illness. The son of the late Mr. Edward Walter Mackey, of Erdington, he pursued his professional studies at Queen's College, Birmingham, afterwards becoming physician and Professor of Materia Medica and therapeutics at the Queen's Hospital in that city. He was also at one time physician to the Birmingham and Midland Counties Hospital for Sick Children. On going to Brighton he was appointed assistant physician to the Sussex County Hospital, and honorary physician to the Royal Alexandra Hospital for Children at Brighton. Dr. Mackey enjoyed a large consulting practice at Brighton and was widely respected.

LITERARY NOTES.

As the result of investigations extending over a period of many years Sir Almroth E. Wright, M.D., F.R.S., has written a book which Messrs. Archibald Constable will shortly publish for the use of students using the microscope. Hitherto this instrument has been too commonly treated by rule of thumb, and without those considerations of the principles of microscopic technique which are so essential to the attainment of accurate and scientific results. The object of the book is to show how best to get from any class of instrument the highest degree of satisfaction in proportion to its range. The text of the whole book goes hand in hand with experiments. The work also contains a complete vocabulary of technical terms relating to the microscope.

***

A clever little book has been brought out by the Lemco Company, called "New Dinner and Luncheon Dishes." In it are described the many uses that "Lemco" may be put to, uses which strike us as being as ingenious as we have no doubt they are appetising.

***

REVIEWS OF BOOKS.

PATERSON ON GASTRIC SURGERY.(a)

Mr. Herbert Paterson has amplified his Jacksonian Prize Essay and issued it, with additional references, in book form, under the title of "Gastric Surgery." The book is divided into two parts, a first part consisting of three lectures, and a second part containing details of the operation of gastric jejunostomy including preparation and after treatment, and ten tables of collected cases showing the after results of gastric operations. These tables are a valuable addition to the literature of gastric surgery and must have entailed a great amount of labour. In the first part we have a well-reasoned argument in favour of the surgical treatment of gastric disorders, "hæmorrhage," and "cancer" being particularly well handled. The book is, as it were, written round the operation of gastro-jejunostomy, the anterior method being recommended, though Mr. Paterson's reasons may not seem conclusive to all. He very rightly insists on the necessity of a wide anastomotic opening, and he considers regurgitant vomiting and peptic jejunal ulcer to be due to insufficiency in this respect. There will be a considerable difference of opinion on the suggestion that an immediate gastro-jejunostomy should be done in cases of perforated gastric ulcer, and it is very doubtful whether the performance of gastro-jejunostomy would justify one in omitting to look for and close a second perforation. In the case of ulcer near the pylorus, where invagination may be impossible, we are, however, quite in accord with the author in the necessity for a gastro-jejunostomy if the patient's condition will allow. The book is clearly printed, is easy to read, and, with its many references, will prove of value to those interested in this branch of surgery.

(a) "Gastric Surgery." By Herbert J. Paterson, M.A., M.B., B.C. Cantab., F.R.C.S.Eng. London: Ballière, Tindall and Cox, 1906. Pp. 112, with appendix 1906.

EXPERIMENTAL BIOLOGY OF AQUATIC ANIMALS. (a)

South-west Germany is fortunate in having at the present time a number of talented investigators, who are concerned with problems more or less of a biological nature. J. V. Uexküll belongs to this group, and the book before us which he has written is one of great interest, replete on every page with facts given in an original and attactive way. The work does not claim to be nor is it a full account of the biology of aquatic animals. The author very commendably confines himself to his personal experiences in a field which he has evidently well worked.

The book begins with an introductory part in which the scope of experimental biology (as contrasted with that of zoology or physiology) is defined. It then passes on to consider the "Reflex" at considerable length, regarding it as a response to the influences of environment. The treatment of this fundamental biological function is original and admirable in every way. Incidentally, it may be mentioned that the view of the structure of the nervous system adopted is that known as the "neuro-fibrillar."

The second part of the work contains a condensed account of "Methods," in which a description is given of certain special apparatus useful for the holding and observation, &c., of aquatic animals. The book ends with short notes of the series of animals mostly invertebrates, upon which observations are to be made.

Altogether, it is a work of convenient compass which will amply repay perusal by the biologist, the zoologist, and the physiologist alike. It is to be hoped that an English translation of it will soon appear.

ALLBUTT'S PROFESSIONAL EDUCATION (b).

This address is now for the first time published in full, as only about two-thirds of it was delivered by the author at the time. The theme of the essay is Medical Education in London. No one is able to speak with greater authority on this subject than the author. For our nation, he thinks that a State portal, in the directest sense, would be too cold-blooded, and might indeed, become too rigid for us. In the United Kingdom, at least the State should entrust the testing of medical efficiency to certain medical corporations under the supervision of the General Medical Council, and its tests should be for safe practice rather than for large attainments. Allbutt regrets that not every student of medicine has the opportunity of having a university education. He considers five years all too short a period for training and preparation with a view to the student's life-work. He refers to the fact that the old pill and bottle of our forefathers is being menaced by newer methods such as massage electricity, hydropathy, the sanatorium, the Nauheim business, and so on, methods which are often beyond the scope of the family physician. He concludes with the somewhat pathetic remark that at his time of life he may never again address so important a body of students as those of King's College, and therefore feels it his duty to touch upon certain matters relating to the higher life without which we can never prosper either as a nation or as individuals.

This essay is well worth reading if only with a view to finding out how one who has spent his life in the interests of medical science looks now at the position of professional education as existing in this country. Allbutt knows how to write, and his words carry weight. It were well if educational authorities as well as students and practitioners laid to heart the many words of wisdom contained within this delightful book.

(b) "On Professional Education. With special reference to Medicine." An address delivered at King's College, London, on October 3rd, 1905. By T. Clifford Allbutt, M.A., M.D., F.R.S., etc., Regius Professor of Physics in the University of Cambridge. London: Macmillan and Co., Ltd., 1906. 2s. net.

MEDICAL NEWS IN BRIEF.

British Medical Association.

THE 74th annual meeting of the British Medical Association will be held at Toronto, Canada, on August 21, 22, 23, 24, and 25 next, under the presidency of Dr. Richard Andrews Reeve, Dean of University of Toronto Faculty of Medicine. This will be the second time that the association has met in the Dominion. Thirteen scientific sections have been arranged, and will meet daily in the University buildings at 9.30 a.m.—namely, anatomy, dermatology, laryngology and otology, medicine, obstetrics and gynæcology, ophthalmology, pædiatrics, pathology and bacteriology, physiology, psychology, State medicine, surgery, and therapeutics. On Tuesday, at 2.30 p.m. an address of welcome will be accorded to members, and the ceremony of introducing the distinguished guests and delegates will be performed. This will be immediately followed by the presidential address by Professor Reeve. At 4.30 p.m., in the University quadrangle, a reception and garden party by the president and Mrs. Reeve. At 8.30 an address in obstetrics will be delivered by Dr. W. S. A. Griffith, of London, while at 9.30 the Lieutenant-Governor will receive the members of the association. On Wednesday, at 2.30 p.m., an address on medicine will be delivered by Sir James Barr, of Liverpool; and in the afternoon various garden parties have been arranged. In the evening, at 8.30, an address on surgery will be delivered by Sir Victor Horsley, and this will be followed by a reception, at 9.30 p.m. On Thursday afternoon garden parties have also been arranged, while at 7.30 p.m. the president will preside at the annual dinner, when a most distinguished gathering is assured. On Friday afternoon extensive entertainments are promised to members and their friends, while in the evening will be held a grand *soiree*. On Saturday, August 25, several excursions are arranged—to Niagara Power Company's plant, through the courtesy of Sir Henry M. Pellat; to Muskoka; and to Lambton, through the courtesy of the president, Mr. Austin.

Irish Medical Association.

THE Committee of Council met in the Royal College of Surgeons on the 24th ult. They further considered the case of the medical officers of Limerick Union, who had been refused payment of the increase in salary granted by a former meeting of the Guardians, and already sanctioned by the Local Government Board. The law adviser of the Irish Medical Association applied to the Board of Guardians to carry out the terms of the resolution, and stated that they must understand that they had no power to modify in any way the terms of the resolution referred to. The Committee decided that, if necessary, the law adviser be authorised to take proceedings against the Guardians.

London Hospitals Sunday Fund.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held on Thursday last under the presidency of Alderman Sir Horatio Davies. The report of the Committee of Distribution of the Council recorded with gratitude that Mr. George Herring had again offered to add one-fourth to the amount collected in places of worship, as well as to the City collection. The amount of the fund to the present time was £56,303, to which had to be added £3,000, a portion of the legacy of £10,000 left to the fund by the late Mr. Herbert Lloyd, making a total of £59,303. This year 250 institutions had made applications for grants, being two more than last year. The committee recommended the distribution of £57,510, to the 161 hospitals and institutions, sixty dispensaries, and twenty-six nursing associations. Also that the award to Charing Cross Hospital be paid when it is proved to their satisfaction that the result of the special appeal to be made next autumn will enable the committee to carry on the work of the hospital, and that the grant made last year be now paid to the City Orthopædic Hospital, without waiting for the amalgamation to be carried through. Five per cent. of the total sum collected is set apart to purchase surgical appliances. The report was unanimously adopted, and after votes of thanks had been passed to Mr. George Herring for his generous and continued interest in the Fund; to the committee of distribution for the care bestowed in the preparation of the awards; to the Lord Mayor for his devotion of so much time to the well-being of the Fund as president and treasurer; and to Sir Horatio David Davies for presiding, the meeting terminated.

The Caledonian Medical Society.

THE twenty-sixth annual meeting of the Caledonian Medical Society was held at Stirling on July 13th under the presidency of Dr. W. A. Mackintosh of Stirling. There was a representative attendance from both sides of the Border. The honorary secretary (Dr. Macphail of Derby) gave in his report, which showed the membership to be 232, or double what it was ten years ago. Financially also the Society was stronger than it ever had been, and the journal published quarterly by the Society had increased its circulation. Dr. Andrew Little, of Bradford, was elected president for the ensuing year. In his presidential address Dr. Mackintosh spoke of the present position and prospects of the Gaelic language, and his address was an able and forcible plea for the teaching and study of Gaelic. The annual dinner was held the same evening, the menu card, designed and beautifully illustrated with local views by Mr. J. G. Murray, was entirely in Garlic, a motto from Galen in the original Latin, with an old Gaelic translation from a curious and valuable MS. in the president's possession appeared on the frontispiece, which also showed the crest of the Society—an armed Highlander battling with the skeleton Death, and the motto "Is Righ Gach Slan?" The toast of the evening was proposed in a racy and witty speech by the Rev. Lachlan Maclean, Alloa, a well-known celt and poet.

Lady Doctor for St. Helens.

ON July 26th at the meeting of the St. Helens Health Committee the Medical Officer submitted the definition of duties and the draft advertisement for a lady doctor for the borough, who will assist the medical officer of health, and deal especially with the school children. The Chairman said he had asked the doctor to put down the salary at £160, rising to £200 by two annual instalments. This was in accordance with what was being done in other parts of the country, and probably in a year or two they would have to pay more. The proposition was agreed to.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held at 429, Strand, London, W.C., on July 27th. There were present: Dr. de Havilland-Hall, in the chair; Dr. J. Brindley James, Mr. F. S. Edwards, Dr. F. S. Palmer, Dr. St. Clair, B. Shadwell, Mr. Edward Bartlett, Dr. M. G. Biggs and Mr. J. F. Colyer. The accounts presented to the Committee were very satisfactory, showing that in

the past half of the current year the sickness experienced by the Society has been considerably less than in the corresponding period of 1905. The result has been an appreciable increase in the financial strength of the Society, the funds of which now amount to over £200,000. The amount paid away in sickness claims now exceeds £10,000 per annum, and about one-fifth of this is paid in annuities to members who are permanently incapacitated from professional work. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery-lane, W.C.

International Exhibition of Hygiene.

Burroughs, Wellcome and Co. have followed up their successes at St. Louis and Liége by obtaining a gold medal at the International Exhibition of Hygiene held during the months of May, June and July at the Rotunda in the Royal Prater, Vienna.

Army Medical Service Reform.

One part of Mr. Haldane's scheme of Army re organisation has already been taken in hand by the Aldershot Army Corps—namely that referring to the Royal Army Medical Corps service. An experimental field ambulance has been formed, and is now encamped at Frensham, with the 1st Division as a trial. Colonel H. N. Thomson is in command, and the whole hasbeen inspected by the Duke of Connaught. The new organisation promises to simplify medical service in the field.

PASS LISTS.

Royal College of Physicians of London.

At the ordinary quarterly *comitia* of the Royal College of Physicians of London, held on July 26th, the President, Sir R. Douglas Powell, occupying the chair, the following Fellows were elected officers of the college :—Censors.—Frederick T. Roberts, M.D., Sir Thomas Barlow, M.D., J. Mitchell Bruce, M.D., T. Clifford Allbutt, M.D. Treasurer.—Sir Dyce Duckworth, M.D. Emeritus Registrar—Sir Henry A. Pitman, M.D. Registrar—Edward Liveing, M.D. Harveian Librarian—J. Frank Payne, M.D. Assistant Registrar—Oswald A. Browne, M.D. Library Committee—Norman Moore, M.D., William Osler, M.D., Archibald E. Garrod, M.D., Humphrey D. Rolleston, M.D. Curators of the Museum—H. Charlton Bastian, M.D., William Cayley, M.D., W. Henry Allchin, M.D., Seymour J. Sharkey, M.D. The following were elected examiners in the subjects indicated for the ensuing collegiate year :—*First Examination*—*Chemistry*—J. M. Thomson, F.R.S., G. Senter, Ph.D., B.Sc. *Physics*—J. A. Gardner, F.C.S., F.I.C., F. T. Trouton, F.R.S. *Materia Medica and Pharmacy*—C. Ogle, M.B., J. J. Perkins, M.B., R. A. Young, M.D., J. P. Stewart, M.D., O. F. F. Grünbaum, M.D. *Physiology*—W. D. Halliburton, M.D., E. H. Starling, M.D., B. L. Abrahams, M.B. *Anatomy*—P. Thompson, M.D., R. Howden, M.B. *Medical Anatomy and Principles and Practice of Medicine*—F. de H. Hall, M.D., T. D. Acland, M.D., G. N. Pitt, M.D., W. Collier, M.D., H. M. Murray, M.D., N. Dalton, M.D., H. D. Rolleston, M.D., F. J. Smith, M.D., A. P. Luff, M.D., W. E. Wynter, M.D. *Midwifery*—F. H. Champneys, M.D., J. Phillips, M.D., H. R. Spencer, M.D., W. J. Gow, M.D., T. W. Eden, M.D. *Public Health*—W. H. Willcox, M.D., A. G. R. Foulerton, F.R.C.S. The following, having passed the required examinations, were admitted to the membership :—John Telfer Calvert, M.B., Lond., L.R.C.P., St. Thomas's Hosp., Major I.M.S., Bengal; T. E. Cecil Cole, M.A., M.D., Oxford and St. Bart.'s; Henry Roy Dean, M.B., Oxford, L.R.C.P., Oxford and St. Thomas's; G. W. Ross, M.B., Toronto, L.R.C.P., Univ. of Toronto. The Moxon gold medal, instituted in memory of Dr. Walter Moxon, and awarded every third year to the person who should be deemed to have most distinguished himself in observation and research in clinical medicine, was awarded to Jonathan Hutchinson, F.R.C.S., LL.D., D.Sc., F.R.S. The following have been appointed lecturers for the year 1907 :—Milroy, Dr. Leonard Rogers, of Calcutta; Gulstonian, Dr. E. Farquhar Buzzard; Lumleian, Dr. G. H. Savage; Oliver-Sharpey, Dr. Halliburton; Croonian, Dr. W. J. R. Simpson; FitzPatrick, Dr. P. H. Pye Smith. The Bradshaw lecture will be delivered next November by Dr. S. J. Sharkey, the FitzPatrick lectures by Dr. Norman Moore, and the Horace-Dobell by Dr. F. W. Andrews during the same month.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The final examination of the above board, held in Edinburgh, was concluded on July 23rd, when the following candidates were successful:—

Mary Deborah Hancock, Surbiton; Khorshed Sorabji Kanjá, Bombay; John Andrew Kane, Toronto; Thomas McLaren Galloway, Kirkcaldy; Michael Gavin, Dunfermline; Ernest Martin, Alcester; Leonard Clarke Webster, Launceston; William Wallace Dunlop, Edinburgh; David James Melville Legge, Dundee; Henry Albert Pascoe, Durban; Edward Albert Williams, Chester (with Honours); Walter Scott, Canada; John Alfred Steele Phillips, India; Gustavus Herbert Powell, Co. Cork; Leopold Henry Gill, Gibraltar; Patrick Raoul Eskell, Port Elizabeth; John Owen Shircore, India; Thomas Alexander Gregg, Co. Antrim; Carlo Ferruccio Fiaschi, New South Wales; William James Geale, New South Wales; Constance Helena Colley, Ireland; William Dunseith Dickson, Ireland; and Sydney Frank Henderson Everill, Worcester; and two passed in Medicine and Therapeutics, two in Surgery and Surgical Anatomy, twelve in Midwifery, and nine in Medical Jurisprudence.

Royal College of Physicians and Surgeons of Ireland.

Final Professional Examination.—The following candidates have passed this examination :—John Burke, Timothy Alexander Burke, Richard Calnan, Michael John Coyne, Myer Cohen, Joseph Daniel, William Joseph Deighan, Patrick Francis Foran (with honours), Thomas Joseph Galligan, Jermiah Grace, William Glennan, David Gillies, Abraham Hipwell, William Patrick Kelly, Thomas Hunter Massy, Patrick Mullany, William John McCormick, Kevin P. Neary, Joseph O'Donnell, Thomas Thaddeus O'Farrel Dominick Thomas O'Flynn, Gerard Petit, Edward Philip Punch, William Christopher Townsend Robey, Joesph Richard Tobin, William Walsh, Charles Hope Waddell, Mortimer Walters, Joseph Maxwell Warneck, Rupert Weply, Charles Henry Wilson.

Examination for the Diploma in Public Health.—F. W. Brunker, L.R.C.P. and S.I., E.S.R. Cadman, M.D.Edin. F. J. Cahill, R.C.P. and S.I.; Major T. W. Irvine, I.M.S., F.R.C.S. Edin. (with honours); Edward McDonald, M.B., R.U.I.; the Hon. Ella Scarlett Synge, L.S.A., M.D. (with honours).

London School of Tropical Medicine.

The following candidates passed the final examination of the London School of Tropical Medicine, held at the end of the twenty-first session, July, 1906 :—Capt. L. P. Stephen, I.M.S., M.B., Ch.B. (Aberdeen) D.P.H. (Lond.); L. A. Prins, L.M.&S. (Ceylon), L.R.C.P.&S. (Edin.), Colonial Service; Capt. A. W. Cook Young, I.M.S., M.B., Ch.B., D.P.H. (Aberdeen); Major E. Wilkinson, F.R.C.S. (Eng.), L.R.C.P., D.P.H. (Camb.) all with distinction. W. S. Allan, M.B., Ch.B. (Glasgow), R. T. Booth, M.B., B.Ch. (R.U.I.), I. McW. Bourke, M.R.C.S., L.R.C.P., Colonial Service; John Cross, M.B., Ch.B. (Glasgow), Colonial Service; B. M. Flood, L.R.C.P.&S. (Edin.), Colonial Service; E. N. Graham, L.R.C.P., F.R.C.S. (Edin.); E. M. Nicholl, M.B., C.M.(Edin.); J. Ottley, L.R.C.P.&S. (Edin.), (Staff-Surgeon R.N. retired); E. C. Peake, M.B., Ch.B.(Edin.); E. Robledo, M.D. (Colombia, S. America); Miss L. G. Thacker, M.B., B.S. (Lond.), Capt. L. L. G. Thorpe, R.A.M.C., L.S.A.; A. B. Tighe, M.B., B.Ch. (Dublin); W. M. Wade, M.B., B.Ch. (Dublin); Miss K. Wyss, M.D. (Zurich).

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

The Theory of Opsonins.—The literature on opsonins has increased to such an extent, and is at the same time so scattered, that a brief recital of the present state of our knowledge is very opportune. Ross (*British Medical Journal*, July 7, 1906) publishes an address on the subject which is both interesting and comprehensive. Wright and Douglas, as long ago as 1903, showed that the success of the leucocytes as regards phagocytosis, was due, not to any inherent quality, but to the presence in the serum of certain bodies, called by them, "opsonins," which by their action on the invading organisms render the latter an easier prey to the leucocytes. These bodies are specific to the invading organism, and are distinct from bacteriolysins, agglutinins, and antitoxins. In order to estimate the amount of these bodies present, an actual experiment in phagocytosis is made *in vitro*, and the result examined under the microscope. All observations are made by comparison with a normal serum. The ratio of the opsonic activity in the blood under investigation to that of normal blood is spoken of as the "opsonic index." A few general facts have emerged regarding the relation of the opsonic index to infection. If the infection be strictly localised, the opsonic index is, as regards the infecting organism, below normal. If the infection be more general, the index is likely to be more variable, falling from high to low, and rising again, in an irregular manner. A high opsonic index is in itself a sign of a good, though possibly insufficient, reaction on the part of the constitution. The object in the treatment of local infections is to obtain a good reaction, of which the sign most readily recognizable is a high index. The reaction is excited by the inoculation of the subject with a suitable dose of dead bodies of the organism with which he is already infected. The first point, then, to establish in attempting to apply our knowledge of opsonins to the treatment of disease, is to discover the infecting organism. When this has been done, and the opsonic index in relation to it estimated, then a dose of the organism, having been killed by heat at 60° C., is administered subcutaneously. In the case of tubercle, the usual initial dose is one-thousandth of a milligramme of the solid substance (KR), while in the case of staphylococcal and pneumococcal infections, the dose varies from 100,000,000 to 2,000,000,000 organisms. After the inoculation, the index always falls—"negative phase"—but, unless the dose has been excessive, it speedily rises to or above normal. When this has occurred, a second inoculation may be given, the negative phase after the second injection being usually less marked than after the first. On no account should an injection be given during the negative phase, as if this be done the production of opsonins is markedly depressed, and the bodily reaction much lowered. By the introduction of opsonic methods to medicine, an enormous and unexpected extension has been given to vaccine treatment. Formerly, in so far as treatment by tuberculin was a failure, it was so because of the impossibility of regulating the dose. Clinical observation was much too coarse a method, since if an overdose were given the harm was done before it showed itself by clinical signs. In almost every variety of localised infection, the opsonic control of vaccine treatment has proved successful. Ross enumerates some twenty conditions, of which some of the more important are furunculosis, acne, empyema, cystitis, gleet, gonorrhœal arthritis, lupus, tubercular laryngitis, tubercular iritis, tubercular peritonitis. It is not only, however, in therapeutics that the new method is of use; it is of equal value in diagnosis. A normal index, toward any organism, if present on repeated examination, is contra-indicative of the presence of that organism as an infective agent. Some of Wright's experience bearing on this point is almost sensational in its justification, even in the face of apparently certain clinical evidence. The reader who wants at once an intelligible and concise account of the relations of the opsonic theory to diagnosis and therapeutics, cannot do better than consult Ross's paper. We could wish that Wright himself would find time to summarise and systematise his own contributions in a small volume, which would take its proper place as the classic authority. At present his papers are scattered, and hard to obtain, so that many people are at a loss to know where to turn for information.

R.

The Serum Treatment of Dysentery.—Since the definite establishment by Shiga, in 1898, of a bacillus as the specific cause of one form of dysentery, there have been many attempts to produce a serum with protective or curative properties. The most successful worker was Rosenthal, who, by the injection of the serum of horses, immunised by inoculation with dysenteric toxin and live bacilli, reduced the mortality during an epidemic in Moscow from 10 per cent. to 4.5 per cent. His serum was also used with encouraging results during the Russo-Japanese war. Thus, of fifty-nine patients with dysentery treated by Barikin in Manchuria, only one died, and he was moribund when he came under treatment. Vaillard and Dopter have published recently (*Annales de l'Institut Pasteur*, May 25th, 1906), particulars of researches conducted by them at the Pasteur Institute which carry our knowledge of the subject some steps further. In the process of immunising horses they employed alternately live bacilli and toxin in increasing doses. The toxin was obtained by filtering through porcelain a broth culture of the bacilli, which had been kept for twenty days at a temperature of 37° C. The toxicity of the filtrate is such that a fourth of a cubic centimetre, when introduced into the veins, kills a rabbit of two kilograms weight in twelve to sixteen hours. The preventive and curative properties of the serum were tested on rabbits, and it was found that a suitable dose gave complete protection against a lethal dose of both cultures, even when the administration of the latter was delayed for as long as two days. Similarly, if the administration of the serum followed the infection by a period not exceeding twenty-four hours recovery took place. If the period were longer, recovery was not certain. The authors then made use of the serum in the treatment of ninety-six cases of dysentery, only one death resulting. The curative efficacy of the serum showed itself in the almost immediate alleviation of local and general symptoms and in the rapid recovery of the patients treated. The authors believe the following conclusions justified: (1) The serum of horses immunised against the dysentery bacillus possesses anti-microbic and anti-toxic properties; (2) This serum is harmless, even in massive doses, and is a specific treatment for bacillary dysentery; it is without effect in other forms of the disease; (3) Injected in doses which should vary with the gravity of the case, it produces immediate amelioration and rapid cure; (4) Its effects are the more marked the earlier it is given in the course of the disease; (5) The serum ought to be employed without delay in all cases of dysentery which are not known to be amœbic in origin.

Antirabic Vaccinations at the Pasteur Institute.—Viala (*Annales de l'Institut Pasteur*, June 25th, 1906) gives the statistics of the persons treated against hydrophobia during the year 1905 at the Pasteur Institute. Of the 728 persons treated, four died of hydrophobia. Excluding one who died before the treatment was concluded, this gives a mortality of ·41 per cent. The mortality fluctuates greatly from year to year, the highest being ·94 per cent. in 1886, the first year of the Institute, and the lowest ·18 per cent. in 1902. The number of persons treated has shown a fairly steady diminution during the twenty years' existence of the Institute, a diminution accentuated of late years by the establishment of antirabic institutes at Lyons, Marseilles, Bordeaux, Lille, and Montpellier. Of the four persons who died, one had been bitten by an animal whose rabies was established experimentally; two by animals whose rabies was certified by a veterinary surgeon; and one by an animal which was not identified. The particulars of the last case are interesting. The patient, a child of seven, was bitten on December 24th, underwent treatment from December 31st to January 17th, showed symptoms of the disease on April 26th, and died on May 3rd. Three other persons who were bitten by the same animal were treated at the Institute, and did not develop the disease. All the persons in whom hydrophobia developed had been bitten on the hands or face. All those treated were natives of France with the exception of two from England, one from Belgium, and one from Holland. R.

Recent Researches in Leprosy.—Long as leprosy has been known to the world, we are still quite behindhand in our knowledge of its pathology. Although there is no doubt as to the identity of the causal organism, yet it has not up to quite lately been cultivated, nor have animals been inoculated with it successfully. In both these particulars it is probable that a definite advance will soon be made. Nicolle (*Annales de l'Institut Pasteur*, May 25th, 1906) describes certain experiments made on apes, which he thinks justify the following conclusions: (1) Certain of the lower monkeys, in particular the *macacus sinicus*, show a manifest sensitivity toward inoculation with leprous material; (2) experimental leprosy in monkeys requires a long period of incubation; (3) the only successful mode of inoculation is subcutaneous; (4) the receptivity of animals increases when they are subjected to repeated inoculations. Nicolle agrees with Weil in his researches on the cultivation of the leprosy bacillus. Each thinks he has succeeded in obtaining some growth, but only when active young leprous tumours have been employed for inoculating the tubes; attempts at sub-culture have been uniformly negative. R.

Larvæ in the Human Intestine.—Though of common occurrence in cattle, the presence of larvæ in the human intestine is sufficiently rare to render each recorded case of interest. Cattle reports (*British Medical Journal*, July 14th, 1906) what appears to be an authentic case. A young man, æt. 19, complained to him of passing insects in his fæces, and presented for examination large numbers of flattened, fusiform larvæ, about 5mm. in length. These were examined by Professor Cave, of Nottingham, who identified them as of the family *Oestridæ*, or "botflies." One species of this family is parasitic in the gastro-intestinal tracts of horses, and another in the frontal sinuses of sheep. The mode of infection of Cattle's patient remained undiscovered. R.

Actinomycosis with Foreign Body in the Abdominal Wall—Cuff (*British Medical Journal*, July 21st, 1906) publishes an interesting case of actinomycosis of the abdominal wall, in which a piece of straw was discovered. The disease gave rise to a firm fibrous tumour involving the ascending colon and the anterior abdominal wall, and containing several small cavities filled with yellow pus. One of these spaces was much larger than the others, and contained the fragment of straw. Microscopic examination revealed large numbers of filaments of the ray fungus. It appears that the patient had been in the habit of picking his teeth with a straw, and it is almost certain that he swallowed an infected fragment which afterwards traversed the intestinal wall. Such fragments have frequently been found in actinomycotic growths, both in men and animals, especially if the jaws or neck be the seat of the disease, but they are much rarer in abdominal infections. R.

The Formation of Tubo-Ovarian Cysts.—Handley (*British Medical Journal*, June 30th, 1906) reports a case of tubo-ovarian cyst formation which throws a light on the pathology of that condition. Operation was undertaken on account of a fluctuating tumour rising from the pelvis above the umbilicus. It proved to be a tubo-ovarian cyst. The left tube, after running a course of about three inches from the uterus, opened into the cyst by an opening the size of a threepenny bit. The cyst was not uniform in appearance, the inner part being yellowish in colour, and showing the remains of atrophied plicæ. The outer portion was quite smooth of surface and pale in colour. The ovary was not to be found. An examination of the right side furnished the key to the origin of the condition on the left. The outer part of the right tube was distended into a hydrosalpinx, which had burrowed in the ligament until it reached the ovary. Within the ovary, and only separated from the hydrosalpinx by a thin septum, was a single cyst, the size of a small orange. Handley thinks that the condition on the right side was merely an earlier stage in the formation of tubo-ovarian cyst than that on the left. He thinks that in such cases, the ovarian cyst is produced by the pressure of the hydrosalpinx interfering with the ovarian circulation, both lymphatic and venous. Any small existing cyst or corpus luteum may thus give rise to a large cyst if the lymph pressure be sufficiently increased R.

The Relative Physiology of the Uterus and Ovaries.—Bond (*British Medical Journal*, July 21st, 1906) has undertaken a series of experiments in the rabbit to investigate the changes occurring in the ovaries when a part or the whole of the uterus is removed, and, conversely, in the uterus when a part or the whole of the ovaries is removed, and in one ovary when the other is removed. Some twenty-eight experiments were performed. Bond thinks the following conclusions, among others, justified:—(1) The presence of active ovarian tissue is necessary for the preparation of the endometrium as a nidus for fertilised ova; (2) the presence of uterine tissue is not essential to ovarian function; (3) there is some antagonism between the saline secretion of the endometrium and that portion of the ovarian secretion which is concerned in producing changes in the endometrium preparatory to the imbedding of fertilised ova; (4) after removal of a portion of ovarian tissue, the remaining portion undergoes hypertrophy; for this hypertrophy, however, certain stimuli are necessary, viz., repeated copulation or pregnancy; the hypertrophy is similar to that which normally occurs in the ovaries during early pregnancy. R.

Calcification of the Seminal Vesicles.—George (*Journal of the American Medical Association*, July 14th, 1906) publishes a case of complete calcification of the seminal vesicles and partial calcification of one vas deferens. The condition is a rare one, the number of recorded cases being small, and the pathology is still a question of some doubt. George thinks that two quite distinct changes may give rise to the condition—(1) chronic inflammation, as from gonorrhœa, and (2) retrogressive metamorphosis of the muscular coat. R.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

C. M. B.—The order of the Privy Council containing the present rules of the Central Midwives Board until February 12th, 1907, was issued on July 31st.

HYGEIA.—The assertion that the underground electric is cooler in summer than the above-ground one is disproved by the fact that a large part of the electric energy delivered to the motors on the train is converted into heat. Also the rail friction, the atmospheric resistance, the brake friction, and all absorbtion of energy must re-appear as heat.

DR. G. (Bristol).—The question of fees to medical men called in by midwives has come up many times before the Central Midwives Board, but nothing is yet settled. A speedy decision is necessary, as many of the poorer classes use the services of unqualified women rather than those of a midwife, who is obliged by law to call in a medical man whom they may have to pay.

DR. H. (St. Ives).—It is well to make very thorough enquiry into the disadvantages of a post in the Seychelles. From the accounts of doctors who have lived there, there is a considerable amount of *ennui* even for a studious man, and the common table foods, such as milk and butter are not easily obtainable.

AIX-LES-BAINS.—The laws regulating the reception and habitation of tuberculous patients at Davos are those formulated in 1901. They can be had by writing to the Hotel de Ville, Berne.

BARON MUNCHAUSEN AND THE PHYSICIANS.

A CORRESPONDENT at Liverpool writes us that, having two versions of "The Travels of Dr. Munchausen" which differ materially in some parts, he is anxious to know which contains the correct skit of the College of Physicians? In reply we may mention that the first edition was issued in pamphlet form in 1785, but this we are informed is inaccessible. The second was printed at Oxford in the following year with little or no alteration. Edition after edition appeared subsequently with "sequels" and other alterations, and the original is now unobtainable. If either of those in the possession of our correspondent bears the date 1786, he may take it for granted that he has the correct verson and that it is of considerable value. The original is in the British Museum, and if our correspondent is anxious to compare his with it he can do so; or we can publish a copy of "The Skit" in our next (it is only about twenty lines) if necessary.

MR. A. W. S.—The regulations have been greatly altered of late; it would be safer for you to write to the Registrar for a copy of the new schedule.

MEDICAL INSPECTOR.—The present anxiety about school children is the natural re-action after years of neglect. Certainly it is good to have eyes tested, but the most real psychosis connected with eye-strain is that shown by certain enthusiastic oculists who have become obsessed with the idea that eye-strain forms the back-ground of most pathological conditions.

MEDICO-LEGAL.—There is an Institute of Forensic Medicine and Psychiatry in connection with the Paris School of Medicine. Foreigners who have studied law in a University in their own country may be admitted to the courses. Possibly, as you are going to practise in France, you might be allowed to join.

M. O. H.—Last year the question of exchanging stale loaves for new ones among the poor came up before the London Master Bakers' Protection Society, and they expressed a desire to aid in putting down a system which, seeing the loaves are often kept on open shelves in dirty rooms, cannot fail to be productive of disease.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 8th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m. Dr. Ball and Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Medical Diseases of Children. 2.15 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations.

THURSDAY, AUGUST 9th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2.15 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations. Mr. Dunn: Diseases of the Eye.

FRIDAY, AUGUST 10th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10.30 a.m. Dr. Moullin: Gynæcological Operations. 2 p.m. Dr. Ball and Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.15 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY, AUGUST 11th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m. Dr. Ball and Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.15 p.m. Medical and Surgical Clinics. 2.30 p.m. X-Rays. Operations.

Vacancies.

Royal Infirmary, Bradford.—Qualified Man to Visit the Home Patients, Assist in seeing Casualties and in the administration of Anæsthetics. Salary £100 per annum, with board and residence in the Infirmary. Applications to Edmund Forster, Secretary.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, &c. Applications to Albert Edward Booker, Clerk to the Guardians, Union Offices, Westbar, Sheffield.

Worcester County and City Asylum.—Third Assistant Medical Officer. Salary £130 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Powick, Worcester.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Sherburn (Ancient) Hospital, near Durham.—Medical Officer. Salary £300 per annum, house, coals, &c. Applications to the Master, Sherburn House, near Durham.

Bracebridge Asylum, Lincolnshire.—Senior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Clerk to the Visitors, W. T. Page, Jun., Esq., Bank Street, Lincoln.

Royal Cornwall Infirmary, Truro.—House Surgeon. Salary £100 per annum, with board and apartments. Applications to J. C. R. Crewes, 4 Paravedras Terrace, Truro.

Stroud General Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Hon. Secretary at the Hospital, Stroud, Glos.

Southwark Union, London.—Second Assistant Male Medical Officer at the Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing.—Applications to Howard C. Jones, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.

Liverpool Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary £120 per annum, with board, washing, and lodging at the Hospital. Applications to the Port Sanitary and Hospitals Committee, Town Clerk, Municipal Offices, Liverpool.

The Royal National Hospital for Consumption for Ireland.—Matron. Salary £75 per annum, with board, &c. Applications to Secretary, 13 South Frederick Street, Dublin.

Fermanagh County Infirmary, Enniskillen.—House Surgeon. Salary £52 per annum. Applications to C. Wilson, Secretary.

Appointments.

CROWE, J. T., L.S.A., Resident Assistant Anæsthetist at St. Mary's Hospital.

CURTIS, WILFRED, L.R.C.P. and S.Edin., L.F.P.S.Glasg., District Medical Officer by the Liskeard (Cornwall) Board of Guardians.

GOODALL, EDWIN, M.D.Lond., B.S., F.R.C.P.Lond., M.R.C.S., Medical Superintendent at the Cardiff City Asylum.

HILL, W. BERTRAM, M.B., Ch.B.Vict., House Surgeon at the Leeds General Infirmary.

KEANE, D. J., M.B., B.Ch., B.A.O., R.U.I., Medical Officer for Enniskillen Union Workhouse, Limerick.

KNIPE, GEORGE W., M.B., B.Ch., B.A.O., R.U.I., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Assistant Medical Officer at the Sick Asylum, Hendon.

LEEDHAM-GREEN, CHARLES, M.B.Birm., F.R.C.S.Eng., Honorary Surgeon to the Queen's Hospital, Birmingham.

MURDOCK, W., M.D.Edin., Certifying Surgeon under the Factory and Workshop Act for the Annan District of the county of Dumfries.

Births.

MUDIE.—On July 30th, at York Lodge, West Norwood, the wife of Arthur Mudie, L.R.C.P.Edin., &c., of a son.

Marriages.

HANNA—ATKEY.—On Aug. 2nd, at Holy Trinity Church, Cowes I. of W., William Hanna, M.A., M.B., Assistant Port Medical Officer, Liverpool, to Sybil Christian, third daughter of the late Joseph Henry Atkey and Mrs. Atkey, Cambridge House, Cowes.

ROCHE—CLERICY.—On July 31st, at the Westminster Catholic Cathedral, Redmon John Roche, M.R.C.S., L.R.C.P., of 18 Bessborough Gardens, S.W., son of the late John Redmond Roche, of Dublin, to Angèle Marie Catherine Clericy, daughter of the late Ange Pierre Jacques Clericy and of Madame Clericy, of Cap Mare, Mentone.

Deaths.

CAMERON.—On Aug. 1st, at 64 Great Portland Street, London, Anne Cameron, widow of the late George Fenton Cameron, M.D., J.P., aged 83 years.

NORCOTT.—On Aug. 4th, at 9 Grosvenor Hill, Wimbledon, William Boyle Norcott, M.R.C.S.Eng., aged 86.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, AUGUST 15, 1906. No. 7.

NOTES AND COMMENTS.

Swansea Doctors' Libel Action.

At the Glamorgan Assizes last week was tried an action for libel brought by Dr. H. St. Thomas against Dr. T. D. Davies. The two gentlemen had been in partnership, but a short time ago it was thought better that this should be dissolved, and that each should practise on his own account. An appointment, that of medical officer to the Cwmfelin Steel and Tinplate Company, had been held by the firm, and when it was dissolved, a ballot was taken among the workmen as to which doctor they would have. The voting was in favour of Dr. Thomas, and the disappointed candidate was alleged to be concerned in the getting up of a petition against Dr. Thomas, a petition which was so unfortunately worded that Dr. Thomas felt he must take steps to clear himself in respect of certain statements. The case came on for trial in due course, and twice during the hearing it seems that the two sides nearly came to an agreement; but though the judge tried to accomplish this end, he was unsuccessful. Eventually the jury found for Dr. Thomas, and gave him £50 damages. Judgment for this amount and costs were entered by the judge, but an injunction which Dr. Thomas sought was refused. The case created a good deal of local interest, and we cannot help feeling sorry that the parties failed to adjust the dispute privately, for it is always a pity when members of liberal profession have to drag their differences into the light of day.

Medical Slander Action.

An equally regrettable slander action was tried at Birmingham Assizes between Dr. T. B. Bradley (plaintiff) and Dr. T. K. Williams (defendant). Dr. Williams had bought a practice at Pensnett, near Dudley, which had at one time been carried on by the plaintiff's father, Dr. Bradley himself at the time not being qualified. It seems that when he had passed his exams, Dr. Bradley set up in practice in Pensnett, and was appointed medical officer to several clubs previously held by Dr. Williams, lower rates of remuneration being accepted. A meeting of the district ethical society was held in March, and Dr. Bradley, who was not a member of the society, was asked to attend, and the matter of charges was discussed. The meeting, it appears, adjourned to allow Dr. Bradley time to consider his action, but the next day Dr. Williams' wife wrote a notice and put it up in her husband's waiting-room, saying that Dr. Bradley had been severely censured by the leading doctors in Dudley. Other charges were made against Dr. Williams, but the notice, which was only hung up for an hour, and for which Dr. Williams offered to apologise, was obviously incorrect, and the jury awarded the plaintiff £10 damages. Here again we can only say it is lamentable that these matters should come to the public courts.

Friendly Societies and Consumption.

At the annual sessions of the Foresters' High Court held at King's Lynn last week, Brother Farris, of London, introduced the subject of the provision of sanatoria for the treatment of members and their families. He showed how largely the funds of the society was taxed by the ravages of consumption, and he thought special means should be taken to reduce the claims. Brother Marlow, Parliamentary agent, however, spoke strongly against the efficacy of open-air treatment, he having had personal experience of it in his own family. The meeting was evidently strongly against taking any special measures, and Brother Farris' motion was defeated by a large majority. While it is undoubtedly true that sanatoria are far from being all that could be desired in the treatment of consumption, we think the Friendly Societies would do well to study the German insurance societies' figures. The matter is not one to be lightly decided one way or another.

The Royal Commission on the Poor Laws in Ireland.

It appears to be a trait of the present Irish Government to prefer the politician to the practical expert as a member of the numerous Royal Commissions which have been created with so free a hand. The latest example of this is the exclusion of a representative of the Irish medical profession from the Commission appointed to inquire into the workings of the Poor-Laws. Not only was such a representative excluded when the Commission was originally constituted, but, even when a vacancy occurred owing to the death of the O'Conor Don, a non-medical man was appointed, although the attention of the Chief Secretary had been drawn to the importance of the inclusion of a professional representative. We are glad to see that the Royal College of Physicians of Ireland have now taken the matter up, and that at a meeting held last week it was

decided to approach the Chief Secretary for Ireland, and point out to him the importance of the inclusion of a representative of the medical profession in Ireland amongst the members of the Commission. We trust that Mr. Bryce will accede to the request of the College and of the whole medical profession in Ireland. Should he, on the other hand, allow the policy of the exclusion of the practical expert to continue, he cannot complain if the public at large do not attach the same weight to the findings of the various Commissions that otherwise they might have attached.

The Free Portrait Trick—a Warning.

As other medical men beside ourselves may have received from a Mr. Tanqueray a tempting offer in which he undertakes to supply "absolutely free" a life-sized crayon reproduction of any photograph they may wish to send him, and as they may be led to comply with Mr. Tanqueray's ingenuous request, we think it well to let them know the experience of a member of our staff. On the receipt of Mr. Tanqueray's offer, a photograph was sent by way of experiment. Almost by return of post came back an answer informing the sender that the life-sized crayon was ready, and "was one of the finest crayon portraits it was possible to produce." With this letter came a catalogue of frames, and a promise to send the portrait free if a frame were ordered—the lowest price being one sovereign. If a frame were not ordered, the fortunate owner of the "finest crayon portrait it was possible to produce" was asked kindly to send ten shillings to cover packing and carriage. Our colleague then proceeded to make inquiries as to the cost of transmitting a parcel from Paris by parcels post, and ascertained that three pounds could be sent for one shilling and four pence, and almost double that weight for about sixpence more. He accordingly wrote to the enterprising Mr. Tanqueray and offered to send him this sum *plus* one shilling and eightpence to cover cost of packing. To this letter no answer was received. Our advice to others who may hear from Tanqueray is to obtain some substantial guarantee before giving hostages to fortune.

LEADING ARTICLE.

TEACHING OF HYGIENE AND TEMPERANCE.

THE medical profession in its corporate capacity may congratulate itself upon the fact that during the turmoil of the education controversies it has kept discreetly clear of the religious question, and fastened itself resolutely on to the moral and physical. The former has generated much heat and led to little satisfaction to anybody; the latter has been accepted in principle by everyone, and seems in a fair way to lead to very tangible results. When some three years ago the medical profession sent a deputation to Lord Londonderry to urge the importance of teaching hygiene and temperance in elementary schools, we imagine that most medical men expected one of the usual coldly-sympathetic official answers which harassed Cabinet Ministers find so useful in choking off deputations, and that they were correspondingly pleased when they found a positive welcome awaited their representatives. The work of the deputation, however, did not end with their visit to Whitehall, for on receiving Lord Londonderry's reply, they set to work on a memorandum designed to show how hygiene and temperance could be easily and usefully introduced into the school curriculum. This memorandum, with appendices, has now been issued, and it is deserving of close study not only by medical men themselves, but by educationalists in general. We may say at once that the committee have done their work very well indeed. They have not been prolix and tedious, and they have not been brief and merely suggestive, but within the compass of some thirty pages, they have set out in persuasive language all the principles that should be followed and most of the details by which they may be carried home to pupils. Now, it is obvious in the first place that if hygiene is to be properly taught in schools, to be made, that is, what medical men wish to see it made, namely, an integral part of school life, it is necessary that the teachers themselves should be instructed. Even if there be no official or local difficulties in the way, this education of the teachers will, we fancy, prove a stumbling block for several years. Not that we mean particularly to blame the teachers, but rather that hygiene as understood by scientific men is so wholly foreign, and, indeed, antagonistic, to the deas of the present teachers, that we do not think it likely a generation rooted in the notion of grammar and geography constituting the be-all and end-all of "education," can be expected intelligently and sympathetically to teach hygiene. For what hygiene really connotes is set forth in an admirable essay in the memorandum before us, and therein it is shown not to be the didactic presentation of certain facts ascertained by others, but a living science permeating and guiding all education. In fact, the point of the memorandum really is that the day for the old dogmas has passed away, and what is needed now is scientific teaching based on physiological knowledge, and that the education of the child should be a natural and not an artificial education. If the memorandum is adopted by the Board of Education—and Mr. Birrell has shown himself in educational matters at least as broad-minded as his predecessor—we shall find that in a few years' time the youth of Great Britain may come into that scientific heritage which their fathers have won for them, and which the youth of most European and American States have begun to enjoy already. It is not possible in our present limits to indicate more than very roughly the lines on which the memorandum runs, but we shall be satisfied if we say enough to send our readers to the study of the original document. Beginning with infants, the committee show how at three years of age hygiene may be taught, and, indeed, how at that age nothing else than

hygiene should be taught. They run up a graduated course of lessons for each standard which should send the child of twelve or fourteen out into the world with a sense of decency, a capacity for enjoyment, and an ability to shift for himself that would admirably replace the present half-polished aptitude for vice which passes for "education" in many "centres." We make bold to say that if the Board of Education can be brought to a knowledge of the science which they are constituted to supervise, and if they succeed in inculcating the principle of that science into the authorities whom they control, and, moreover, if they can train teachers intelligently to bring up children according to its canons, we shall hear less talk of racial, industrial and commercial supremacy passing from Britain to its rival competitors among the nations.

NOTES ON CURRENT TOPICS.

A Generous Offer.

We hope that our readers will not fail to notice the important letter from Mr. Henry Sewill which we publish in our correspondence columns this week. Mr. Sewill comes forward with a direct practical suggestion with regard to the preliminary steps that should be taken towards the suppression of quackery. He advocates the collection of facts by inquiry, with a view to the instruction of the public and the Legislature, but he is aware that this cannot be done without considerable expense. In order to show that his enthusiasm in the cause is not an academic one merely, Mr. Sewill makes a generous offer to guarantee the sum of £50, if ninety-nine other people will come forward in the same manner. With such a sum, namely, £5,000, at their backs, a committee should be in a strong position with regard to the collection of evidence. It is hardly possible to believe that with such materials as could then be presented to them, the Government would refuse to appoint a Royal Commission seriously to go into the whole matter.

Motor Car Report.

Motor cars have sprung so suddenly upon the nation, and have reached such a pinnacle of popularity that the country finds itself puzzled as to how to take full advantage of the new method of progression and yet guard itself against the undoubted dangers that accompany it. It is just ten years since the Act which allowed mechanically-driven vehicles to ply the public roads was passed, and it is no exaggeration to say that the result has been to change the whole face of town and country life. To no class has the motor appealed more irresistibly than to the medical profession; a trustworthy car means a saving of time, anxiety, and wear-and-tear that cannot be assessed in pounds, shillings and pence. Moreover, it is impossible to regard medical men entirely as private individuals; they are in a practical sense public servants, and if the motor-car enables them to do their work more efficiently, the public gain in corresponding ratio. The Royal Commission on Motor-Cars which has just reported makes many suggestions, perhaps the chief being the abolition of the speed-limit. The arguments for and against this proposal are complicated, and though no one would wish to be unreasonable, there is a strong and justifiable feeling against reckless driving. Such driving must be put down, speed-limit or no speed-limit. But in the question of pace, we think that special treatment might be given to doctors called to serious cases. Only the other day a doctor was fined because in answer to an urgent summons he technically transgressed the law by driving over twenty miles an hour. A man driving rapidly to a case of postpartum hæmorrhage deserves very different treatment to one careering for pleasure down a London street or whizzing carelessly through a quiet village. A point, too, that must be brought before Parliament when the renewal of the Act is under discussion is the differentiation that should apply to the taxation of cars used for pleasure and those used for business, and here again we claim exceptional treatment for doctors.

Bodie Slander Action.

Mr. Justice Grantham who tried the recent action for slander brought by "Dr." Bodie against Mrs. Hudson, enjoys the distinction of being, we believe, the only judge within living memory whose conduct has been called in question by Parliament, and we certainly never remember any judge to whom both the Prime Minister and the leading newspaper publicly hinted at retirement. It has been said that Mr. Justice Grantham would do well to take his pension as gracefully as he can, for his knack of floundering in morasses of his own making has amounted almost to genius, ever since his political services were rewarded with a judgeship. In the case we have mentioned "Dr." Bodie, music-hall performer and electrical "healer," sued Mrs. Hudson the president of the Leeds Invalid Children's Aid Society, because she had made at a public meeting some statements of an unpleasant nature against himself. It appeared that Mrs. Hudson had been misinformed as to two of the facts she stated, or at any rate she was not able to prove them; but although she was technically in the wrong, the jury, we take it, showed their sympathy with her in the unfortunate position in which she was placed by giving Bodie the smallest possible damages, namely, one farthing. Mr. Justice Grantham, in his summing up, is reported to have said that Bodie had a perfect right to do things his own way, that he undoubtedly did a certain amount of good, that he could not be accused of being a quack, and that it was unfortunate that Mrs. Hudson had treated him (Bodie) with contempt. The only comment we can make on the proceedings is that Mrs. Hudson has our sincere sympathy, and that we are glad to see it already suggested in Leeds that her costs should be defrayed by public subscription.

Industrial Accidents.

THE Workman's Compensation Bill, 1906, which is to be passed in the Autumn Session, has in it many points of interest to medical men, but the one that will raise most discussion is the proposal to include certain defined industrial diseases among "accidents," for which the employer is liable to pay compensation. When introducing the Bill, the Home Secretary mentioned five diseases which he proposed certainly to include, namely, anthrax, lead-poisoning, mercury poisoning, and ankylostomiasis, and he has just appointed a committee—on which we regret we do not see Dr. Oliver's name—to consider what other diseases may fairly be grouped with them. This new view of disease constituting an accident from the legal point of view furnishes an example of how science is gradually leavening the conceptions of the time, for the idea that pneumonia is as much an accident as a fracture, typhoid fever as a sprain, or diphtheria as a cut, is the direct outcome of the more exact pathological knowledge of late years. The latest legal definition of an accident is that given by Lord Macnaghten in 1903, when he said that the word accident within the meaning of statutes was "the popular and ordinary use of the word, as denoting an unlooked for mishap or an untoward event which was not expected or designed." This being now recognised, the Courts have broadened more and more the meaning of the word till it is difficult to see where any line can be drawn. Hernia and anthrax have been held to be accidents, and if they, why not every form of disease? The Court which decided some time ago that a medical man who was inoculated with syphilis while attending a confinement was the victim of "disease" and not of "accident" would, we fancy, now have to alter its decision. The loss of the distinction between the two terms, though it follows scientific and logical lines, may, however, be a serious matter for accident insurance companies.

'The Christian Age" and Inconsistency.

WE have received a copy of *The Christian Age*—which, we are flattered to notice quotes some observations of ours—and our attention is drawn to an article entitled "The Consecrated Doctor," by the Rev. Frank de Witt Talmage, D.D. The article, if not very original or profound, is yet unimpeachable in sentiment, and furnishes an eloquent defence of material medicine and human doctors as opposed to the transcendental ideas of healing that occupy such a large space of some men's minds at the moment. The doctor is drawn sympathetically and referred to with affection, a tone we miss in a good many other papers that come under our notice, and we note with interest that St. Paul's direction to Timothy to take a little wine for his stomach's sake is understood by Dr. Talmage to be a hygienic protest against the impurity of Palestine water. But it strikes us as not a little curious that whereas the article concludes—"All honour, then, to our Christian physicians whose calling and office are thus divinely consecrated," that on the opposite sheet is a full-page advertisement of "Antipon." Those who are unacquainted with this preparation will be pleased to learn that "Antipon" is "The Greatest of Corpulence Cures," and if they read the advertisement they will find that *The Christian Age* gives it a testimonial as a permanent cure for fatness and as being a splendid tonic. What sort of "consecration" does the Editor of *The Christian Age* call this?

Belfast Fever Hospital.

ON August 2nd, the Lord Lieutenant and Lady Aberdeen opened the new Belfast Fever Hospital which has been erected by the Corporation on the Purdysburn estate, adjacent to the City. The proceedings were well organised by Dr. King Kerr, Chairman of the Public Health Committee, and his subordinates, and they passed off successfully in every way. Many difficulties have stood in the way of those who wished Belfast to have such an institution, and it is now nearly ten years since practical steps were taken to move in the matter. However, though the intervening years may have been awkward ones for those in charge of the public health of the city, the hospital has been able to benefit by the experience of others, and to adopt all those improvements which have been made in construction and arrangement of late years. Before the plans were prepared Mr. Mackenzie, C.E., the architect, visited the principal fever hospitals in England and Scotland, and he took great pains that the first municipal hospital of Belfast should be worthy of the town, with the result that for its size the hospital is one of the best designed and equipped of its kind. The small-pox hospital which stands on the same site as the fever hospital, and is still only of a temporary character, is situated well away from the other buildings.

The Dangers of Shrimping.

Now that merry Margate, breezy Brighton, and a hundred other coast-towns are inundated with their annual influx of visitors, all the usual seaside fun will be in full swing; and while their elders are soberly seated round bands and pierrots, the children will be disporting themselves on the shore in the ways they have done since time immemorial. But because customs are old they are not like wine necessarily the better, and a severe hand might with advantage be laid on some seaside recreations. Bathing properly conducted is perhaps the most healthful pleasure that children can have, but paddling is open to great objection, and of all forms of amusement shrimping is perhaps the most dangerous. It is a thoroughly unphysiological performance for children to be sent in the hot sun with perhaps only a cap or sun-bonnet on their heads and their legs absolutely bare. As soon as they enter the water chilling of the feet and contraction of the cutaneous vessels occurs, and with the sun beating on their heads a temporary congestion of the

brain and its membranes naturally follows. When hours are spent wading to and fro with a net to catch shrimps this congestion is liable to lead to such an increase of pressure within the skull as to bring on giddiness, sickness and headache. It is fortunate if the trouble ends there, for long-continued illness and fatal results are not unknown. Shrimping, if undertaken at all, should only be indulged in the latter part of the afternoon, and then only for half an hour or so at a time.

Schoo Anthropometry.

The last places that education reaches, as a rule, are those institutions which were founded for the purpose of educating the youth of the upper and middle classes, namely, our public schools. The archaic traditions of the Universities are from time to time modified slightly by the necessities of life, but the public s chools generally go on their way with a cheerful indifference to the needs of their pupils. Now a new science is springing up in our midst, to which the term "school hygiene" is generally given, but which is imperfectly described thereby. The science we mean is that which regards the youth of both sexes as plastic material, out of w hich the best men and the best women have to be moulded for the benefit of the Empire and of the world, and this science is contemptuously disregarded, for the most part, by those who have the moulding of the material. One day, when the Board School pupil begins to demonstrate his superiority to the public school boy, serious notice may be taken of the science of pedagogy; at the present moment it is in the making. A primary requisite of this science is that it should be furnished with exact data on which to work, and we notice with pleasure that University College School, which is less hide-bound by tradition than its more venerable contemporaries, has adopted a system of anthropometry, with a view to marking the changes in the physique of its pupils from year to year. Dr. J. H. Spenser, the head-master, introduced this system into the Glasgow High School when he held a similar position there, and he has now succeeded in putting it into active operation at University College School. Other head-masters would do well to follow his example.

Opticians and Sight-testing.

The question of sight-testing by opticians is still to the fore, and we have before us an article from the *Daily Telegraph* headed "Oculists and Opticians: the Plea for Freedom." in which the old arguments and, we may add, the old misrepresentations, are again brought forward. Opticians are evidently trying to "educate" public opinion in favour of their claim, and it behoves medical men and medical journals to see that the professional view atta in s equal publicity. Let us say at once that in reply to the "Plea for Freedom" that the protection which medical men urge is the protection of the public against improperly-qualified "sight-testers," and not the protection of medical men as against the public. The stock argument of the opticians is reproduced in the *Daily Telegraph* article, namely that whereas medical advice is needed for disease of the eye, defects of the eye can be treated by opticians. To those who know little or nothing about the delicate mechanism of the eye, such an argument may appear to have some force, but let us assure any who may be inclined to accept it, that medicine recognises no defect in the eye that is not the result of disease or of a congenital weakness or deformity, and that if any of these be not treated by proper measures, of which the adjustment of spectacles is only one, irreparable harm may be done. Hypermetropia and myopia, long or short sight, and all defects of vision, are but the expressions of ophthalmic changes, and as such need radical and not merely symptomatic treatment. The other argument used is that the poor and middle classes cannot afford an ophthalmic surgeon's fees. A statement of this kind is either the result of ignorance or misrepresentation. There are hundreds of general practitioners all over the country who are thoroughly competent to diagnose and treat eye-diseases of every kind and who are doing so every day.

PERSONAL.

The King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Mr. Diarmid Noël Paton, Superintendent of the Laboratory of the Royal College of Physicians, Edinburgh, to be Regius Professor of Physiology in the University of Glasgow, in place of Professor J. G. M'Kendrick, resigned.

Surgeon-General W. L. Gubbins, C.B., has been appointed to Lord Kitchener's staff as principal medical officer of His Majesty's forces in India, in succession to Sir Thomas Gallwey, transferred to Aldershot.

Mdlle. Olga Yakovlev, the doctor who opened a free hospital to the poor in Moscow, and who was exiled to Siberia for withholding the names of wounded revolutionaries under her care, is reported to be dying of consumption.

The name of Dr. John Milsom Rhodes appears amongst those of the new county J.P.'s for Lancashire. We are glad that the honour should have been so worthily bestowed.

Professor Clifford Allbutt has been appointed to serve on the Home Office Committee, which is to decide what industrial diseases shall be regarded as accidents for the purpose of the Workman's Compensation Bill which is to be passed in the autumn.

Dr. Buzzi, the Italian physician in attendance on King Charles of Roumania, was lunching with his Majesty at Sinaia on Tuesday, when he had a sudden attack of paralysis. King Charles was much affected.

Dr. Thomas Moorhead, J.P., Cootehill, has been elected President of the Irish Poor-law Officers' Association, and Dr. R. M. Blake, J.P., has been re-elected to the office of Vice-President.

The passengers of the "Empress of Britain," which sailed from Liverpool on August 10th, included Sir William Broadbent and fifty other medical gentlemen bound for the British Medical Association Congress in Canada.

A CLINICAL LECTURE
ON THE
DISEASES OF THE SKIN CAUSED BY INSECTS.

By JONATHAN HUTCHINSON, LL.D.Oxon., Hon.M.D.Dub., F.R.C.S., F.R.S.,
Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and Royal London Ophthalmic Hospital.

GENTLEMEN,—To-day I am going to deal with, apparently, a very simple subject, but, I believe, notwithstanding its apparent simplicity, a very important one—viz., the extent to which animal parasites may attack the human skin and produce skin disease; and to claim that a great number of those diseases, which have received quite special names, and concerning which we have sought out special symptoms, may be referred to the bites of insects. I will commence by showing you a series of drawings, in order that from them you may realise what it is possible for insects to do to the human skin.

Here (diagram shown) is a very formidable-looking thing—a slough and a considerable amount of ecchymosis on the hand of an adult. There are three or four other places on the other hand, not nearly so formidable looking, but representing the same thing at a later stage. The cause of that is known. These hands are the hands of a surgeon who knew the whole history of his case, and who killed the fly which had bitten him and had produced that condition. Unfortunately, he did not keep the fly, but there is no reason to think that these sores on his hand were the result of any dead material or any organic organism in his blood. The bite, I believe, was that of an ordinary gadfly. One peculiarity about the bite of a gadfly is, that if you allow it to subside it goes away in about a week and leaves a papilla which itches for a day or two and then disappears, but at the end of a fortnight recurs. Scabies may be cured and then come back for a time. This does not at all prove that the poison of the insect is still present in the skin; it simply shows that, with regard to these skin diseases, there is a liability to recrudescence.

Here is a drawing (diagram shown) that would puzzle most people for a diagnosis. You see the result not of an insect prick, but of mechanical irritation. You see there a pigmented skin, with a superficial scar, covered with a lot of little scars, this condition having arisen from mechanical irritation caused by the prick of a syringe for injecting morphia.

This drawing (diagram shown) illustrates what is possible in the form of mixed results produced by the action of pyogenic organisms, secondary to the irritation of insects. This is a disease of the skin known as impetigo which, in this particular case, began with irritation produced by lice. Then the part got infected with pyogenic organisms, and, as a result, the disease ran a somewhat different course from what it would otherwise have done.

In this (diagram shown) you will notice little blue patches scattered on the inside of the thighs of an adult man. You will see nits of lice on the hairs of the pubes. That is an eruption acknowledged to be the result of the presence of the pediculus pubis on the skin.

Here is another illustration of skin disease (diagram shown), due to the presence of lice on the pubes. The lice on the pubes do not travel, but remain on the hair.

Here are two diagrams (shown) illustrating the result of bites of insects on the naked skin. These blue patches are a somewhat different eruption to that produced by the pediculus pubis. We in England have comparatively little of that kind of eruption.

This next portrait shows the result of long-continued, repeatedly-recurring pricks of the body louse, pediculus vestimentorum. This is known as vagabond's skin, produced by having lice constantly upon it, and which is characterised by pigmentation and a scar all over.

(a) Lecture delivered at the London Hospital, July 3rd, 1906.

This is another example (diagram shown) of pigmentation from body lice. You will notice scattered blotches all over the thigh. In all cases in which we suspect insect pricks we look to the centre of the papilla, and if there is a centre displaying a little depression, or a minute scar, it is very suspicious of prick from some insect.

Here is an illustration (diagram shown) of what the flea can do. There you see an eruption occurring on the arm of a delicate, fair-complexioned child, and entirely due to fleas.

This diagram (shown) represents a case which I had under my own observation, and I believe the flea that caused these bullæ was subsequently caught and killed. These bullæ are the remains of flea bites, and it is one of the characteristics of eruptions due to parasite bites that you are able to see them in various stages. These bullæ are the result of scratches which leave scars containing blood. What I particularly want to insist upon is that the flea can produce bullæ of large size. This case was that of a child, one of a family of three. His brother and sister were not especially liable to flea bites. It is an interesting fact that some persons appear exceedingly prone to get fleas, whilst others never seem to be troubled with them. This child's grandmother and some of her cousins were remarkably subject to attacks by fleas. Another interesting point is that an eruption caused by flea bites, in children, is often attended by severe febrile disturbance—high temperature and sickness. I remember a family of children, two of whom were in bed for days, not infrequently, with febrile illness. I was in correspondence some years ago, repeatedly with some parents living in Lancashire who consulted me about an eruption from which their child suffered, and which no one could understand. The child would be in good health, and then out would come a severe eruption, attended with sickness and temperature for some time. This occurred every now and again. Several times an appointment was made for the child to be brought to me, but the appointment could not be kept because the child was too ill to come. Finally, however, I saw the child, and found that what it was suffering from was nothing but the result of flea bites. It then had a very severe bullous eruption, attended by febrile disturbance. This case illustrates the severity of a process which may arise from the ordinary prick of a flea, or some other insect, with intent to suck blood.

I now come to ground which is disputable, and I claim that various forms of the disease known as urticaria are very often due to flea bites. Prurigo urticaris, lichen urticatus, urticaria perstans, and urticaria pigmentosa are the result of nothing but flea bites or bug bites. This diagram (shown) represents what so high an authority as Dr. Fox described as lichen urticaris, which, he contends, is a definite disease of itself. My contention is that it is always due to flea bites.

This is an exceedingly valuable portrait (shown) illustrating a supposed case of prurigo urticaris. The patient was a country child who had been quite free from eruption until brought up to London. The child slept one night in London, and next morning was covered with this eruption that you see. Dr. Fox said it was London milk that did it. I think it was the London flea. If you will examine the eruption, I think you will conclude that I am very much justified in holding that opinion. In the centre of every one of these erythematous patches there is a prick, and in

many places the erythema is fading away. Is it at all probable that in a healthy child, brought up to London, a change of diet would, in twelve hours, bring out an eruption like that? The child was made feverish by the eruption, and there is conclusive evidence, borne out by those other representations of skin eruptions which I have shown you, that this particular eruption was due to flea bites. In describing the characteristic bullæ of prurigo urticaris, Dr. Fox mentions that they have little centres. I myself cannot explain the centre of an eruption as due to some article of diet, but I can explain it as due to prick.

Lichen urticatus is a very common eruption, and most frequently occurs across the loins. This disease is especially common on the buttocks and across the loins in children. Those positions are a kind of harbour for lichen urticatus. There is another disease called purpura urticans, in which the eruption is very like the wheal of urticaria, and liable also to hæmorrhage. These two skin affections are caused by the bites of fleas. The bites of fleas frequently produce wheals exactly like urticaria. Before I first came up to London I did not know what a flea bite was, but after I came I thought I had become a subject of urticaria, until I discovered that the eruption on my skin, from which I repeatedly suffered, was due to flea bites. I meet with many persons who have an eruption and do not know in the least what is the cause. I remember a lawyer telling me that at a certain place he always got urticaria. He told me the name of the place, and I have not the slightest doubt that his urticaria was the result of flea bites. The wheal of urticaria gets its name from being like wheals produced by the sting of the nettle. The stings of insects also produce wheals. These wheals generally have a centre, and every now and then that centre will be hæmorrhagic, and then the person affected will get purpura urticans. Here is (in diagram shown) a distinct centre a little discoloured, as the result of a little hæmorrhage into it. Here is another centre which, I claim, is due to a prick. That is an illustration of purpura urticans. Is it an unreasonable suggestion that it is the result of flea bites?

This diagram (shown) illustrates a skin affection known as lentigo lentiginis, or freckles on the nates. This is not an uncommon condition, and I believe it is a remote result of insect pricks. Here (diagram shown) is a typical prurigo. If those other conditions, of which I have already shown you illustrations, are due to insect bites, this also appears to me to have resulted from a similar cause.

Here is an illustration (diagram shown) of an eruption on the buttocks. The buttocks are very apt to be attacked. It is a blotchy eruption, and you cannot see the central points so well, as they are in a fading condition. This eruption puzzled those who were called upon to treat it, but I claim that it is due to bug bites. Between bug bites and flea bites the distinction is very considerable. Flea bites produce an eruption much more like urticaria, the part affected presenting a marked state of congestion and a central puncture. On the other hand, bug bites produce an irregular area of dusky congestion, with nothing exactly like the urticarial wheal. Bug bites are very much more infrequent than flea bites. The bug is very apt to attack the face; it prefers the face, or the scalp, especially of bald-headed men. The bug bite, unlike that of the flea, does not itch intolerably, and very often not at all. A man may have disfiguring blotches on his face, the result of bug bites, without being aware of the fact, until he has made the discovery through the looking-glass. That is very common with bug bites. If an eruption occur on the face, and especially on the bald scalp, then I should suspect bugs much more than fleas as having been the cause. If the eruption is dusky in colour, that fact should confirm your suspicion.

We come next to the consideration of the disease which goes under the name of urticaria pigmentosa. My friend, Mr. Nettle, whose writings are well-known, was the first to describe cases of this kind; he described them at the Hospital for Skin Diseases. Urticaria pigmentosa is now a well-recognised disease, and in this diagram (shown) we have a good illustration of it. The disease lasts for a long time. Here is another illustration (diagram shown) of urticaria pigmentosa in a child. The eruption has a tendency to persist and become pigmented, more or less. This (diagram shown) is another representation of the disease in a boy. The blotchy character of the spots is well shown. In urticaria pigmentosa the face only escapes. Here is another example (diagram shown). You will notice a little hæmorrhage in some of the spots; they represent various stages in the disease. I think you would suspect that this eruption was due to insect bites.

Here is a picture (shown) illustrating the early stage of what is called urticaria papulosa, a skin disease which is also, I maintain, due to flea bites. The history of this particular case would, in all probability, show that flea bites had been the real cause of the eruption. Urticaria pigmentosa almost always begins in childhood though not in early infancy. The child is liable to recurring eruptions, crops of which come and go. When the eruption disappears minute quantities of blood are left behind, which form permanent papules, and these subsequently pigment. The disease persists till nearly adult life, and then the patients almost all get well. We know that liability to attacks by insects diminish as the patient's skin advances in age. The manner in which the eruption of urticaria pigmentosa is arranged, in cases of insect bites, is very important for diagnosis. You will never see any circular patches; the eruption is always irregular, it is never distributed with perfect bilateral symmetry. Complete bilateral symmetry implies blood disease. The irregular eruption of urticaria pigmentosa I have been accustomed to describe as presenting an appearance like the constellations in the sky. Insect pricks run, so to speak, in a straight line, then they run off in different directions, and the area affected presents any shape excepting that of an eclipse or circle. This irregularity and constellation-like arrangement, either in lines or curves and never in accurate circles, is a very important point in connection with diagnosis. The fact of the eruption becoming pigmented is due, I take it, to a peculiarity in the individual.

A very interesting point, confirmatory of my suggestion that urticaria pigmentosa is due to insect pricks, occurs in connection with a case published by Dr. Crocker. He states that a child was taken into University College Hospital, in order that the medical men there might see the initial lesion. But the initial lesion would not come, simply because its cause was not there, and they let the child go home again.

This diagram (shown) represents a case of infantile ecthyma, a disease which is due to pyogenic organisms, but which may easily be developed by scratching eruptions that begin with insect pricks. I would suggest that this was a case of infantile ecthyma, secondary to ordinary flea bites.

Here is a very old drawing (shown) which passes under the name of urticaria pelicalis. Here there has been very considerable extravasation of blood, from thrombosis. There is a good deal of blood staining in these four patches. Our forefathers did not have accurate representations copied from one stage of skin disease in a patient; they often represented different stages taken at different times. That, I would suggest, has been done in this case. Here is another illustration of the same disease in a boy. When I first saw him I noticed two dusky places, with extravasation on his calves. He was in good health. I jumped to the conclusion that these extravasated places had really been due to insect bites. The child had been exposed to the risk of being bitten by insects. This case was evidently an aggravated condition of insect pricks, the aggravation being due partly to the position of the affected places on the boy's legs. This diagram (shown) represents a later stage—a week or ten days later—of the disease, in the same case.

You see here (diagram shown) an illustration of what is known as lichen urticatus. In this case the disease

has become gangrenous, and I claim that it is the result of insect bites. In no other case have I seen such a serious condition due to the bites of insects.

This case of lichen urticatus (diagram shown) has probably been due to the stings of gnats, or of mosquitoes, just such as frequently occur in India.

Here is another illustration (shown) of the same disease which, in this case, has been partly due to scratching, secondary to insect bites.

That is my contention, then, with respect to these various diseases—that before we give learned names and attribute specificity to them, we ought very carefully to examine the evidence as to whether they may not be due to some very simple cause, and that cause an external one. I think I have given you proof that a great many of these skin diseases are due to insect poison. I have also shown you some which so closely resemble those others as to warrant an inference that they are really all due to the same cause.

It is only right to state what are the tests to which the assertion which I have made can be brought. It can be brought to several very useful tests. If, for instance, you suspect that a case of eruption is due to the bites of insects, you should first observe whether the eruption is symmetrical, and then whether it occurs in successive crops. That is extremely important. Cases of urticaria pigmentosa always occur in that way. Then, again, you should ask the nurse whether the eruption makes its appearance at night or during the day. If she says that the child always gets fresh spots during the night, that is very important, because we know that these insects bite chiefly during the night. Of course, people may come into contact with dogs and other animals and in that way get insects which may bite them during the day. But still, the general statement is that the eruption occurs in crops, and these crops occur during the night. Then, if the nurse tells you that the fresh spots do not occur on both sides, but are localised, that is helpful evidence. If the eruption is large, it may be on both sides, but if the fresh spots are always local, that is a very useful symptom.

You ought not to allow the fact that the child is ill or feverish to be any reason whatever against the eruption being due to insect bites.

The last test will be to take the child away from its surroundings, to take it to the hospital, for instance, where it will be under cleanly conditions, and then observe whether the eruption recurs. If the eruption is a seaside eruption, it is very suspicious. A child may get an eruption when visiting a farmhouse; he may go into the henhouse and may there be stung by a particular insect, and if he is bitten by it, there is a possibility of his getting an eruption which may mislead anyone. These, then, are the particular tests which I am quite willing to submit.

I would impress upon you the importance of making your diagnosis carefully, and if you are satisfied that the eruption is due to insect bites then use your insect powder and let the child's skin be anointed with a little lotion destructive to insects. But do not tell the nurse the cause of the eruption, or else you will lose your patient. The fact that the child has fleas may not be the result of carelessness in the least, but if you mention that cause to the parents they will resent it. I remember one case which I had, and the mother said, "What is it?" "I will not tell you. I am sure, if I tell you, you will not believe it." "Oh, yes, I will believe anything you tell me." "Well, it is all due to flea bites." "No, I'm quite sure it's not!"

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Jonathan Hutchinson, LL.D., Oxon. and Cantab., Hon. M.D. Dub., F.R.C.S. Eng., F.R.S, Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and the Royal London Ophthalmic Hospital on "Tuberculosis and Diseases of the Skin," delivered at the London Hospital, June 26th, 1906.*

ORIGINAL PAPERS.

BRADYCARDIA.

By JOHN HAY, M.D., M.R.C.P.,

Physician, Stanley Hospital, Liverpool; Physician, Hospital for Consumption and Diseases of the Chest, Liverpool.

THERE is a form of bradycardia termed "paroxysmal" or "intermittent." Two varieties are described:—

1. In which the pulse is permanently infrequent, and there are sudden accesses of greatly diminished frequency.

2. Where the pulse is of normal frequency between the attacks.

The case which I shall now relate belongs to the first variety. The following are the important points to be noted in reference to it —

1. Marked bradycardia, the pulse frequency ranging from 17 to 30 per minute—*à pouls lent permanent.*

2. Transient loss of consciousness, associated with cessation of the pulse at the wrist.

3. Auricular contractions, occurring twice or thrice as frequently as the ventricular—the cause of the bradycardia being "heart block."

4. An enormous heart; the autopsy revealing no cause for the hypertrophy and dilatation.

I give a brief résumé of the case.

R. M., æt. 26. Healthy till May, 1898, when he suddenly lost consciousness. Some time later he was admitted to the Royal Infirmary, under the care of Sir James Barr, to whom with Dr. Raw I am indebted for permission to publish the case. On admission he complained of breathlessness on exertion, and attacks of unconsciousness.

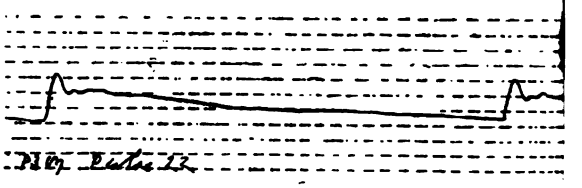

FIG. 1.
Pulse tracing taken by Sir James Barr. Rate, 20 per minute.

On January 8th, 1900, he entered Mill Road Infirmary suffering from extreme cardiac failure. He died on January 15th, 1900. When he was in the Royal Infirmary I noted the following points:—

1. The apex beat was situated outside the nipple line, slow, heaving, and forcible in character, 20 beats per minute.

2. Pulsations or small beats, 50 or 60 per minute, occurred regularly over the 3rd left intercostal space, just to the left of the sternum.

3. Synchronous pulsations were observed in the veins of the neck.

4. Definite systolic retraction in 3rd, 4th, and 5th left intercostal spaces.

5. Cardiac dulness (deep) extended 7 inches to the left, 2 inches to the right of the middle line.

6. Systolic murmur at all areas, loudest and harshest over conus of the right ventricle. It was conducted to the left, and was heard along the vertebral border of the scapula.

7. No sounds were audible accompanying the small pulsations above mentioned.

8. Pulse varied from 17 to 30 per minute.

Fig. 1 is a pulse tracing taken from this patient.

The cardiogram (Fig. 2) demonstrates the slow rhythm of the ventricle, and the more frequent rhythm of the auricles. When the contraction of the auricle coincides with that of the ventricle, it is masked by the record of the ventricular contractions. The waves in the venous pulse tracing are seen to be synchronous with those of the cardiogram. The tracings show, therefore, the two independent rhythms, auricular and ventricular.

The pulsations visible over the conus of the right ventricle were due, in my opinion, to the strong right auricle forcing blood through into the right ventricle, the ventricle being in disastole and permitting the impact of blood to make itself evident by a slight movement of the chest wall over the conus.

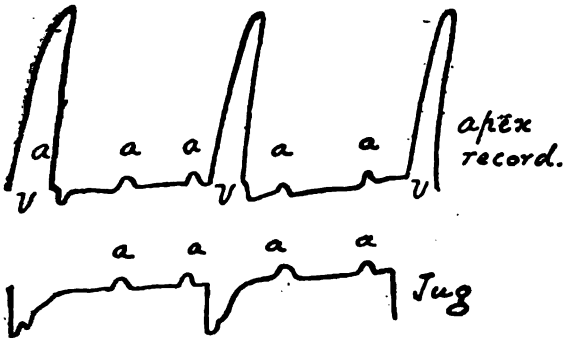

Fig. 2.

Shows that the auricles have a rhythm independent of and different from that of the ventricles.

a=movement of the lever due to contraction of the auricles.

v=movement of the lever due to contraction of the ventricles.

The upper tracing is a cardiogram, the lower is a record of the pulsations in the jugular vein.

Later, when admitted to Mill Road, it was noticed that the cardiac dulness (deep) had increased to the right by one inch; that the only murmurs persisting were a marked tricuspid regurgitant, and a faint mitral regurgitant, and that the frequency of the pulse had reached 40 to 80 per minute.

The autopsy, to my astonishment, gave us little assistance. The area of deep cardiac dulness as previously determined was mapped out on the chest, and its correctness proved by the insertion of long needles at right angles to the surface. To the right the needle was found to have entered the pericardial sac without touching the heart; at the apex the needle just entered the edge of the left ventricle, thus demonstrating that the deep cardiac dulness as elicited ante mortem was correct. Pericardium normal. The heart weighed 29 ounces, showing marked hypertrophy and dilatation. Valves all translucent, and normal in appearance. Tricuspid valve very incompetent. Mitral valve also incompetent. Liver "nutmeg." Kidneys weighed 15 ounces, and on microscopical examination were found to be normal except for signs of back pressure.

Some weeks ago I sent the heart to Professor Arthur Keith, of the London Hospital, for his opinion. With exceptional kindness he has drawn a diagram showing the condition he found and more particularly that of the auriculo-ventricular junction. I reproduce the diagram (Fig. 3).

From the report with which he favoured me I quote the following:—

"The two marked changes in your specimen (besides the hypertrophy and dilatation of the chambers) are: (1) Stretching of the auricular canal (the portion normally within the auriculo-ventricular groove); (2) Separation, or rather attenuation, of the bond between the bases of the valves (tricuspid) and base of the ventricle."

Remarks.—This is an undoubted example of "heart block."

Normally the stimulus to contraction is initiated in the remains of the sinus venosus, consisting of the musculature at the mouth of the great veins, and adjoining portion of the right auricle.

The wave of contraction spreads over the auricle and through the auricular canal on to the ventricle "with varying speed, quickest over the tissue, which has become modified so as to approach more nearly in its properties to ordinary striated muscle, namely, the reticulated bulged portion of the auricle and ventricle; more slowly over those parts which retain a more embryonic character, namely, the auriculo-ventricular muscular ring and the bulbus arteriosus."

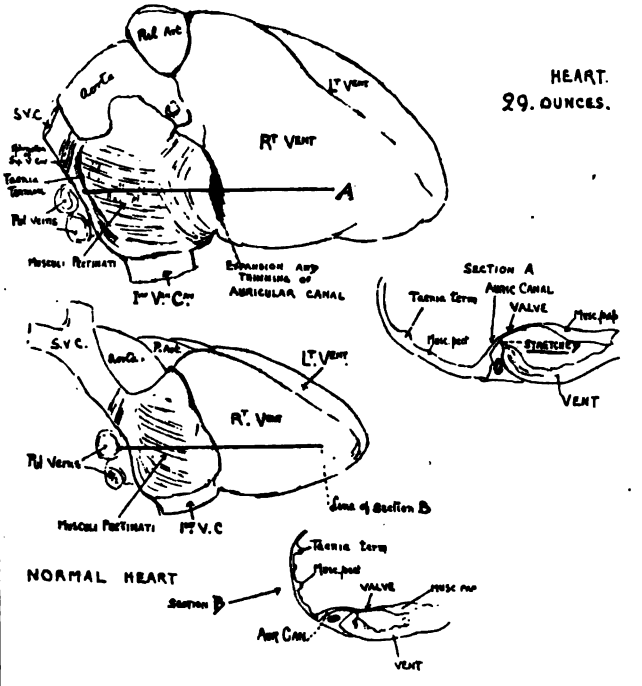

Fig. 3.

Diagram drawn by Professor Keith. It compares the heart of the patient with a normal heart, and demonstrates the condition present at the auricular canal. (Drawn to scale.)

Normally, the ventricle responds to a stimulus spreading down to it from the auricle; if by any means the ventricle is cut off from this normal periodic stimulus, it tends to initiate its own stimulus, and to take on a rhythm different from and independent of the auricle. Gaskell demonstrated this in the frog's heart by ligaturing the auriculo-ventricular groove so that no stimulus could cross from auricle to ventricle. The term "heart block" is applied to this condition.

A heart in which the auricle dominates the rhythm as a rule, beats with normal frequency. When the stimulus for ventricular action arises in the ventricle itself there is a slow rhythm. The result of "heart block" is therefore bradycardia. Such a condition we find in this case; the block in all probability takes place at the attenuated portion of the ventricular wall situated at the base of the ventricle, at its junction with the auricular canal. This attenuation, described by Keith, could not fail to involve the auriculo-ventricular bundle of His, the only muscular connection between the auricles and ventricular and thus the "pathway of the stimulus to contraction" would be damaged.

An interesting question arises as to the cause of the great hypertrophy and dilatation. It is too great to be satisfactorily accounted for by the strain of work. It is not due to chronic nephritis. There is no sclerosis of the valves. The incompetency of the mitral and tricuspid valves must be in some degree responsible, but it pertains rather to the later stages than to the period of comparative compensation, when, as we have already noted, there was a transverse cardiac dulness of 9 inches.

I suggest the following explanation. Since, during each ventricular diastole, the auricles contracted twice or thrice, the resulting condition in the ventricles would

be one of over-distension, and they would during their systole have an excessive amount of blood to deal with. The strain on the ventricular walls due to the forcible pumping of blood by the auricles would produce dilatation, and the large volume of blood to be dealt with would necessitate hypertrophy.

The discussion of this case would be incomplete if it did not include a brief reference to the "attacks of unconsciousness" of which he complained. Twice on March 23rd it was noted that during an attack of dizziness his pulse became imperceptible, returning gradually to its normal rate of 20 per minute. I believe that this cessation of ventricular systole explains these attacks of unconsciousness, and brings this case into line with the more pronounced forms of "Adams-Stokes syndrome."

We may conclude, then, that in the case I have described the bradycardia was due to a condition of heart block—so complete that the auricles and ventricles beat independently of each other.

There are other cases, however, in which the block in the auriculo-ventricular bundle of His is not complete, and where the ventricles respond to every second contraction of the auricles, or even to every third or fourth contraction.

Quite recently I had the good fortune to meet with such a case in which the bradycardia was caused by a severe depression of conductivity, the ventricle failing to respond to every second contraction of the auricle. The patient I refer to is æt. 62. His occupation up to the present illness was that of baker. This entailed the carrying of heavy loads up and down stairs. He denied syphilis or alcoholic excess. The present illness began three years ago with a sudden loss of consciousness. Since then he has occasionally suffered from "mazy bouts." The doctor in attendance told me that when he first saw him eighteen months ago he noticed that the pulse was 20 per minute; there was then some bronchitis, with considerable dyspnœa, The extremities were cold, but there was no cyanosis or œdema.

Since that time his pulse had remained persistently infrequent and the bradycardia probably dates from then.

I was surprised at the healthy appearance presented by the man. He had good colour and was well nourished but there were signs of deficient aeration of the blood in the hands, which were very cold, and, according to the patient, became livid and numb on the slightest exposure. He felt perfectly well, with the exception of great dyspnœa on exertion. His area of cardiac response was limited. His chest was distinctly emphysematous. The radial and temporal arteries were uniformly thickened and tortuous. His pulse rate was 32 per minute—the pulse regular in force and frequency, of large volume and good tension. I noticed two beats in the neck to each radial pulse and tracings demonstrated this fact. On analysing the records, it is seen that the auricular beats occur at regular intervals and that every other beat is followed by the carotid pulse. It is almost impossible to record the venous pulse in the neck without at the same time recording the carotid. This is rather an advantage than otherwise, as it gives us a fixed point in the analysis of the tracing in the record of the jugular vein; the distance from the beginning of the contraction of the auricle to the first appearance of the carotid beat corresponds roughly to the time between the auricular and ventricular contraction. This interval is called the a-c interval, and is normally about 1-5th of a second in duration.

Where, however, there is depression of conductivity, and the stimulus finds greater difficulty in passing from auricle to ventricle the a-c interval is lengthened.

It is so here. Instead of being 1-5th of a second, it is 2-5ths.

On analysing the tracing we find first an auricular contraction 'a^1' followed by the carotid pulse 'c,' and note the a-c interval as double the normal length. Then we meet with another wave due 'a^2' to a second contraction of the auricle, but this time there is no sign of ventricular response. The stimulus has not been

FIG. 4.

E = the sphygmic period, or period of ventricular systole, as shown in the radial pulse, and as shown in the tracing from the jugular.
a^1 and a^2 = Auricular waves in the tracing.
c = Carotid pulse recorded simultaneously with the venous pulse.

able to reach the ventricle. This sequence is repeated without variation in all the tracings.

To demonstrate the action of the heart when Fig. 4 was taken, I have constructed the diagram Fig. 5. It is built on the plan adopted by Wenckebach and Mackenzie. The down strokes in the upper division, AS represent the auricular systoles and correspond with the waves "A" in Fig 4, while the down strokes in the lower division, VS, represent the ventricular systoles and correspond to the radial and carotid pulses in Fig. 4. The short thick lines connecting these down strokes represent the passage of the stimulus through the fibres joining auricles and ventricles. In this case they are 2-5ths of a second in duration—that is, double the normal length. The absence of this line indicates that the stimulus has failed to pass these fibres, and hence a ventricular systole drops out.

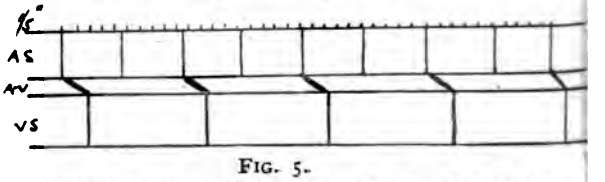

FIG. 5.

Diagram constructed to show the action of the heart when Fig. 4 was taken.

The heart is little, if at all, enlarged. The deep cardiac dulness measures 1½ in. to the right, 4 in. to the left of the middle line. It was difficult to hear the heart sounds at the base owing to emphysema. At the apex I made out a wheezy systolic bruit, followed by a clear second sound, and then, during the diastole of the ventricle, and synchronous with the extra pulsation in the neck, I heard a short whiffing murmur due, I believe, to the auricular systole forcing blood into the partially filled ventricles.

THE last stage of a Swansea Valley controversy took place on July 31st, when a Local Government Board inquiry was held at Pontardawe into the circumstances of the re-appointment of Dr. Griffiths as medical officer of health, after a previous decision of the council not to reappoint him.

AMONGST those present at the annual dinner of the Medico-Psychological Association of Great Britain were the Bishop of St. Albans, Lord Monkswell, Sir Ralph Knox, Sir Owen Roberts, Mr. Justice Walton, Canon Swallow, and Sir Edwin Cornwall, M.P.

CEREBRO-SPINAL MENINGITIS.*

By CARLOS FRANCA, M.D.,
Of the Faculty of Medicine, Lisbon.

Of the many varieties of meningitis, epidemic cerebro-spinal meningitis is the only one that constitutes a well-defined morbid entity with its own peculiar symptomatology, its pathological anatomy and specific micro-organism. All the other forms are meningeal localisations, either of some common bacillus or of the infective germs of other diseases.

Whatever organism happens to obtain a foothold in the meninges, it invariably gives rise to reactional inflammation manifested externally by a symptomatology which does not necessarily vary with the particular agent to which it owes its origin. True, there are certain slight differences to be noted between the other forms of meningitis, but the general picture is the same whether we have to deal with a case of tuberculous meningitis, epidemic cerebro-spinal meningitis, a pneumococcal or a streptococcal meningitis.

In epidemic cerebro-spinal meningitis several clinical types may be observed. The commonest form is that in which the onset of the disease is sudden, with headache, vomiting, fever and sometimes convulsions. Then, on the second day, we get stiffness of the neck or opisthotonos, Kernig's sign, photophobia, and delirium. These symptoms persist for several days, and then there supervenes a period of remission of the fever. The disease runs on for two or three weeks, with repeated exacerbations of the headache and fever until the temperature subsides by lysis. This marks the commencement of convalescence, and is perforce somewhat protracted on account of the damage to which the meninges have been subjected.

Another clinical form is the malignant variety, in which the disease supervenes with crushing violence; is associated with hæmorrhagic changes in the skin, and in which the general conditions rapidly go from bad to worse. In this form we are early confronted with grave disturbances of respiration and circulation, the patient falls into a comatose state and succumbs in from twenty-four to thirty-six hours.

Lastly, there are chronic forms, relapsing forms, in which the patient appears to be entering upon convalescence, but the disease persists for several months with alternating phases of remission and exacerbation. Throughout the whole duration of the affection, Weishselbaum's diplococcus is found in the cerebro-spinal fluid.

In tuberculous meningitis the clinical aspect also varies a great deal in certain cases. Thus, in infants at the breast, the prodromal period is often wanting, and, on the contrary, the onset may be sudden, with convulsions or hemiplegia, followed by a semi-comatose state, which culminates in death in the course of four or five days. In adults and young people the disease may commence with some solitary symptom which persists alone for a long time. In such case, as soon as the other symptoms present themselves, the disease usually runs a rapid course.

Although the progress of the disease sometimes allows of our establishing a differential diagnosis between tuberculous meningitis and other forms of the disease, this is impossible in the vast majority of cases, unless we have recourse to lumbar puncture. By no other means can we scientifically determine the particular variety of meningitis under observation.

In marked contrast with the pronounced poverty of the normal cerebro-spinal fluid in figured elements, meningitis is always associated with a comparatively well-marked leucocytosis. The most interesting feature of this leucocytosis is the extreme variety of the cellular elements present, for, according to the case, this or that micro-organism tends to predominate.

In epidemic cerebro-spinal meningitis the cerebro-spinal fluid is, to begin with, rich in polynuclear leucocytes, and polynucleosis is the most marked feature of the acute stage of the meningitic process. Later, if the disease persists, it is not unusual to witness a change in the histological character of the fluid. The cells with polymorphous nuclei become fewer and give place to lymphocytes and mononuclear cells. In such cases, when there is an exacerbation of the morbid process, a further augmentation in the proportion of polynuclear cells takes place.

Cytological examination of the cerebro-spinal fluid in cases of tuberculous meningitis gives very different results. Here lymphocytosis predominates, while polynuclear cells are only present in comparatively small numbers.

We have bacteriologically examined some 271 cases of epidemic meningitis, and in every instance we have found Weishselbaum's *micrococcus intracellularis*. It is worthy of note that in such an extensive epidemic as that of Lisbon, we only met with three cases in which the meningitis was due to any other organism. In one instance it was the pneumococcus, once the streptococcus and once the staphylococcus.

What may be termed the classical treatment of meningitis consists in the use of baths at a temperature of 104 °F., but the painful contraction of the neck muscles renders the bath treatment very distressing. Lumbar puncture, on the other hand, is well borne, and determines a tangible improvement. In the first place it diminishes the pressure of the cerebro-spinal fluid, and in the second place it is the means of getting rid of a large number of microbes with their toxic products. It is therefore the most rational mode of treating epidemic meningitis, and the reason why certain authorities have failed to develop any enthusiasm about this mode of treatment is that they have not employed it in the proper way. In order that the puncture may have a well-marked therapeutical action, a large quantity of liquid must be withdrawn, and the intervention should take place as soon as the symptoms point to a heightening of tension. If we proceed in this way, making one or even several punctures daily, in the early stage, we obtain very encouraging results.

Epidemic meningitis is a disease in which the morbid agent is localised in the meninges, and but rarely affects the blood. It was therefore very reasonable to seek to deal with it by the introduction of antiseptic substances into the subarachnoid space, and we have been enabled to satisfy ourselves that this procedure presents the following advantages:—Disappearance of relapses, which are so common in meningitis, a

* Abstract of paper read before the Fifteenth International Congress of Medicine, held at Lisbon, April, 1906.

marked curtailment in the duration of the affection, prompt disappearance of the diplococcus, but moderate loss of flesh on the part of the patient, absence of marked trophic disturbances, and lastly, infrequency of mental troubles, and paralyses and lesions of the organs of special sense which are so frequently affected in meningitis.

In grave cases we have employed subcutaneous injections of ether for the purpose of stimulating the hepatic cells, which are often damaged in meningitis. Cold enemata were also ordered daily and calomel in purgative doses. When albumen was found in the urine, we applied dry cupping over the loins with copious administration of lactose, whereupon the albumen soon disappeared. The patient's diet calls for the closest attention, but should be on a liberal scale.

In tuberculous meningitis the only useful treatment is lumbar puncture, which, at any rate, affords relief. In some cases I have injected antiseptics into the spinal canal but without any beneficial effect.

When we are dealing with a toxic meningitis, lumbar puncture, employed whenever there are signs of compression, gives excellent results. By this means we not only hope to obtain a cure, but to avert hydrocephalus, which is often a late complication of these forms of meningitis.

With regard to the treatment of suppurative cerebro-spinal meningitis of otitic origin, our first care must be directed to the treatment of the auricular lesion.

THE OUT-PATIENTS' ROOM.

ROYAL EAR HOSPITAL.

Deformities of the Nasal Septum.

BY MACLEOD YEARSLEY, F.R.C.S.

AMONGST the out-patients was a male, æt. 33, who for the past two years had been suffering from frequent colds in the head with considerable nasal obstruction. He stated that his tendency to nasal catarrhs had existed for some ten years, but the affection had been worse during the last two. Morning dryness of the throat and a husky voice were prominent symptoms. On examination there was marked granular pharyngitis, the nose showed a septum greatly deviated to the left side, the concavity on the right being occupied by a greatly enlarged middle turbinal body. Mr. Yearsley remarked that more or less deviation of the septum was said to occur in 75 per cent. of all cases of nasal obstruction. It was an interesting fact, he thought, that nasal obstruction was far more common in civilised nations than amongst savage tribes; indeed, according to Morel Mackenzie and Zuckerkandl, a comparative examination of skulls showed that nine out of ten civilised individuals had abnormal noses, whilst those of four out of five savages were normal. A large number of theories, he pointed out, had been advanced to account for this frequent septal deviation, but many of them were erroneous and some of them fantastic. The causes of deviated septum could be reduced to two heads—(1) trauma or injury and (2) faulty growth. Injury might, of course, occur at any age, and, considering the number of falls and blows on the face to which children were exposed, it was not to be wondered at that injury accounted for a large number of cases; probably deviations of the septum would not be so common if more care were taken of nasal injuries in childhood; all such cases, especially when accompanied with much bruising or violent bleeding, should be examined under an anæsthetic and any displacement properly rectified. Deformities of the septum, save those due to injury, were extremely rare in children. It should be remembered, he said, that the septum was not fully developed until at least the age of puberty; indeed, the centre of ossification of the perpendicular plate of the ethmoid did not make its appearance till that time, consequently one had a soft yielding developing structure during the years of childhood which was liable to be injuriously acted upon by any pathological conditions in or about the nasal chambers. In Mr. Yearsley's opinion the most potent cause of faulty growth of the septum lay in repeated nasal catarrhs. Colds in the head were such frequent occurrences that people habitually neglected them, instead of looking upon them as serious disorders requiring treatment. The result was that every cold left its mark upon the nose, and generally more in one nostril than the other. A repetition of such colds sooner or later ended in more or less unilateral nasal obstruction. Since obstruction meant a negative pressure in the obstructed nostril, it did not require much thought to recognise how faulty growth of the septum resulting in deformity could be induced. In children the prevalence of adenoids, so prolific a cause of nasal catarrhs, was probably as, or even more, productive of septal deformity as injury.

Mr. Yearsley pointed out the varieties of septal deformities, a matter, he said, very inadequately treated in the text books. The most common form was that in which there was a double angle formed by an anterior vertical deviation joined below at an acute angle with a second and horizontal deviation, passing from below upwards and backwards and frequently involving the bony septum. The next most common was the single angled deviation formed by the horizontal deflection similar to the one just described, but without the vertical deformity. Then came the S shaped deflection, which might be either horizontal or vertical. Finally there was the C shaped deformity formed by one large bulge. There were also other less common deformities. A fairly frequent condition was that deformity due to dislocation of the septum from the columella. A large number of the so-called spurs or ridges were in reality due to slight deviations thickened at the apex.

The amount of obstruction to nasal breathing caused by septal deformities varied greatly. It must not be forgotten, Mr. Yearsley said, that septal deflections might be complicated by enlargements, complete or partial, of one or other turbinal, by adenoids or by synechiæ. In the present case obstruction was very considerable and was further complicated by enlargement of the middle turbinal on the side of the concavity. How was such a patient to be relieved? Only by surgical interference. The number of operations which had been devised for the rectification of deviated septa was very large. He would mention Asch's operation and Moure's method, which were well known; they were both only adaptable to certain forms of deformity. Many rhinologists were content to rectify a deviated septum by forcible smashing with appropriate forceps, with or without the aid of a nasal saw, followed by the wearing of splints. Recently a more scientific method had been introduced known as the submucous resection operation. This was what Mr. Yearsley proposed to do for the present case. It consisted in the raising of a large muco-periosteal flap and the complete removal of the whole cartilaginous and bony septum. The result was a straight septum, consisting of fibrous tissue covered by the nasal mucosa. In the present case this would have to be preceded by the removal of the enlarged middle turbinal.

OPERATING THEATRES.

ST. PETER'S HOSPITAL.

EXTERNAL URETHROTOMY. — MR. SWINFORD EDWARDS operated on a man, about 35, who had been admitted to the hospital with difficulty of micturition. He had been attending the out-patient department

for two weeks, during which time several attempts had been made to pass an instrument but without success; indeed, every attempt was attended with considerable hæmorrhage. It was hoped that under an anæsthetic a pilot bougie might be passed, thereby enabling internal urethrotomy to be performed. The patient having been anæsthetised, several varieties of pilot bougies, both straight and corkscrew, failed to reach the bladder. An attempt was then made to pass a Maisonneuve's urethrotome without the pilot, but this and likewise several steel bougies also failed even when aided with a finger in the rectum. The operator then had recourse to various whip bougies, but as these failed and considerable hæmorrhage was occasioned it seemed apparent that the tract of the urethra had been left and some false passage entered. Perineal section was therefore decided upon, and the patient placed in the lithotomy position. A Wheelhouse's staff having been passed down as far as it would easily go—namely to the region of the triangular ligament—an incision was made on to this in the usual manner. The end of the staff being exposed it was thrust through the wound, the upper extremity of which was thus held up. The external walls of the incision were now pulled apart by pressure forceps, but no urethra was seen at the bottom of the wound; it was therefore clear that the staff had passed into the false passage which had thus been laid open. After some few minutes spent in search of the urethra, it was found lying to the left of the false passage; the urethra was opened and a bougie passed onwards into the bladder without any difficulty. The staff was now withdrawn and one or two attempts made to pass it from the meatus into the urethra, which had been laid open, but unsuccessfully; so a fine gum elastic bougie was passed in the opposite direction, that is to say, from the wound, out through the meatus; this was accomplished without difficulty. The end of the bougie was now securely fastened to the extremity of a No. 12 Condé catheter by means of silk; in this way the catheter was brought through into the wound, the guide bougie next detached, and the catheter passed on through the proximal portion of the urethra into the bladder aided by the finger in the wound; the incision in the urethra was closed by a fine catgut suture as far as possible. Another layer of buried sutures brought the deeper parts together, especially in the anterior portion of the wound. A few silk-worm gut sutures were also used to approximate the edges of the wound, except at its posterior or under part, into which a drain was passed with some gauze packing. The operation was completed by fixing in the catheter in the usual way. Mr. Edwards remarked on the difficulties attending this case. He said that it was unusual to meet with a false passage opening into the urethra as far forward as had been met with in this case; indeed, he estimated that this lesion was situated within three inches of the meatus and it was clear that the hæmorrhage, which had attended all attempts at catheterism, had been due to the instruments passing into this false passage, which had tunnelled the corpus spongiosum urethræ. During the operation, no real stricture had been encountered, though it was possible that the patient might have suffered with some form of congestive stricture in the penile urethra. The operator further remarked that this must be considered as quite an unusual case and must have been occasioned by injudicious attempts in the way of too much force having been used at catheterism before the patient presented himself at the hospital. Ninety-five per cent. of the cases of stricture in which operation was necessary were, he said, submitted to internal urethrotomy at this hospital, for where a guide could be passed through into the bladder it could almost certainly be followed by the urethrotome. The chief thing was to have a good supply of guide bougies, both straight and of the corkscrew pattern; a properly made pilot bougie, which might be of various sizes from No. 1 to No. 4 French gauge should not be too flimsy or string-like, but should have a certain amount of backbone approaching to some extent the character and consistence of the whalebone bougie, but these, he admitted, were not always easy to be obtained. The reason that he preferred internal to external urethrotomy in cases of stricture was because in the first place there was less risk to life and in the second place the convalescence was much more speedy, being in the proportion of one week for the internal as against four for the external operation, the records of the mortality after the internal operation as practised at St. Peter's being not more than 2 per cent.

It was satisfactory to note that the patient was doing well, and was on the high road to recovery.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 12th, 1906.

Created Abscesses.

The creation of abscesses had been recommended for the first time by Fochier, in 1895. The beneficial *rôle* of local lesions, says Prof. Lemoine, in general infectious diseases seemed to him to justify the method. He first tried it in puerperal fever by injecting from 15 to 30 drops of essence of turpentine beneath the skin. He provoked thus an abscess which seemed to arrest the disease. The experiments of Fochier were followed by those of Dieulafoy, Bard, Lépine, in 1897. These authors applied the method with success to pneumonia and broncho-pneumonia, typhoid fever, cerebro-spinal meningitis and erysipelas. Chanteuress and Rendu, on the other hand, seemed to derive no benefit from it, but the reason was that they employed the method *too late* after all other means were exhausted, and as a sort of *pis aller*.

The success of Carles, Prieur, Courtin, in broncho-pneumonia, and that of Probst in cerebro-spinal meningitis proved beyond doubt the utility of the creation of local abscesses in the above affections.

Prof. Lemoine, for his part, had applied the method in several cases of suffocating catarrh, with surprising success. The injections never exceeded a cubic centimetre at the time, but it was repeated the following day in two or three cases. The region chosen was the external portion of the thigh or the side of the thorax. The injection is very painful, as it provokes a circumscribed phlegmon, but may be relieved by warm, moist compresses. The pus is formed in five or six days, and the abscess may be opened towards the eighth day, but it heals very slowly.

The mode of action of these abscesses is difficult to elucidate, but Dieulafoy and Laverau believe that under their influence a regular mobilisation of leucocytes which crowd the lungs occurs, directing them into the general circulation.

The creation of an abscess, says Prof. Lemoine, is an heroic method which should be employed in grave general affections, which ordinarily terminate fatally.

Puerperal fever, suffocating catarrh, and cerebro-spinal meningitis, are the cases which justify the method on the condition that it is employed at an early date, and is never attended with dangerous consequences when ordinary antiseptic precautions are taken.

Pneumonia and Camphor.

The treatment of pneumonia by camphor, given by

the mouth or injected subcutaneously, is strongly recommended by Dr. Scheffler. The hypodermic injections should be reserved for cases where the heart is failing, and the solution employed is that of camphorated oil (1 in 10). One or two injections daily. The camphor, however, would seem to have a more effective action when administered by the mouth:—

Camphor, 15 grs.;
Tincture of chinchonæ, 1 drachm;
Glycerine, 1 drachm;
Syrup of tolu, 4 ounces;
Syrup of orange, 1 ounce;
Water, 5 ounces.

A tablespoonful every hour. The camphor acts as a tonic of the nervous system.

TUBERCULOUS GANGLIONS OF THE NECK.

General treatment: Live in the open air as much as possible, sleep with window open at night, substantial diet, cod liver oil, arsenic, cacodylate of soda.

Local treatment:—

Iodide of baryum, 4 grs.;
Iodide of potassium, ½ drachm;
Axonge, 6 drachms.

Injections into the ganglion of—

Fowler's solution, 1 drachm;
Distilled water, 1 drachm.

Inject two drops into the ganglion and wait two or three days to allow the local reaction to subside. At the end of a week, inject four drops.

The treatment is tedious, and only succeeds when the ganglion has a tendency to soften.

The best treatment of all is radiotherapy, but it should be done by a specialist, unless one possesses a complete installation for the production of the X-rays. The main idea in the treatment by this method is to cause to be absorbed as many rays as possible in maintaining the integrity of the skin, and this can be effected by allowing sufficient intervals between the séances. Eight days should be allowed between the two first séances, twelve days between the second and third, and fifteen days between the others. The first effect of the treatment is a kind of softening of the pourtour of the ganglion. The ganglions separate and diminish in volume by the formation of cicatricial fibrous tissue.

How long should the treatment last? Seven or eight weeks. If at the end of that time no effect has been observed, it might be continued for another similar period; and if there was still no result, it should be abandoned and the arsenical injections renewed.

Besides the local action, radiography produces an improvement in the general condition; sleep becomes better, the weight increases, the appetite improves strength returns and the blood becomes modified. Radiography requires a great deal of prudence on the part of the operator on account of possible accidents: erythema, pigmentation of the skin, falling of hair or beard, headaches.

GERMANY.

Berlin, Aug. 12th, 1906.

[FROM OUR OWN CORRESPONDENT.]

AT the Society fur Innere Medizin, Dr. v. Leyden showed

(1) PREPARATION OF KIDNEY DISEASE AFTER LEAD INTOXICATION.

Slight albuminuria, he said, often came on even after only short handling of lead; cases of chronic nephritis passing on to contracted kidney were more rare. The patients passed copious quantities of urine with symptoms of stasis and dropsy. The urine resembled that of contracted kidney in having a low specific gravity, containing but little albumin and sediment The sufferers gradually became worse, dyspnœic, and died, with symptoms of uræmia and collapse. The man from whom the preparations were taken was æt. 40; he had suffered from lead colic even as early as his twenty-second year. Six months ago asthmatic troubles began, through which he had to give up work; the specific changes in the blood corpuscles could not be determined. The patient was very much reduced on admission into hospital, pale and dyspnœic. Some days later he died somnolent and suffering from dyspnœa. The autopsy showed the heart to be greatly hypertrophied, but not dilated, as was usually the case; on one wall was a marianthic thrombus on the trabeculæ, plainly a result of diminished activity of the heart. Such pure hypertrophy was observed but rarely. The kidney showed red granular atrophy, a number of glomeruli were contracted, others were degenerated. Amongst the latter the capsule was thickened, the vascular loops were degenerated and red, there was no epithelium or cells in them. There were also glomeruli that were intact. The intervening tissue was increased and extended by pure connective tissue fibres. The canaliculi were partly contracted but little altered in structure. The vessels showed thickening and narrowing of their lumens. The thickening affected the adventitia, the narrowing of the lumen was due to thickening of the intima; there were no signs of inflammation. There was therefore no proper nephritis in the case, but a disease of the renal blood vessels, with subsequent contraction of the kidneys. The disease differed, therefore, from the usual form of contracted kidney. The disease and its symptoms were similar to that described by Traube in his day.

From all this, the setting up of forms of kidney disease from their ætiology that could scarcely be distinguished by their symptoms was justified. A distinct contraction of the kidney was not always met with, but only one of the renal and vascular systems.

(2) GENERAL METASTASIS OF CANCER AFTER OPERATION FOR MAMMARY DISEASE.

The case was that of a woman, æt. 40, delicate and pale, whose breast had been removed for cancer two years before. There was a smooth round cicatrix, and the regionary glands were not swollen. The patient complained on admission of trouble in the chest, and the X-rays showed shadows in two places that might represent tumours. She remained a long time without any special trouble, even improved a little, and then an affection of one eye began, with pain and diminished power of vision. On examination, a small white, probably carcinomatous, tumour was found on the retina. Similar symptoms then appeared in the other eye, and here also Greef found a tumour on the retina. One day the patient became worse, complained of violent headache, and died quickly. The autopsy showed a surprisingly and rarely met with condition. At the spot where the mamma was amputated there was a smooth cicatrix, no recurrence, metastatic nodules the size of walnuts were present in the lungs, as shown by the X-ray shadows. Nothing abnormal in either heart or liver. In the brain there were a large number of small metastases, well over twenty, which were associated with the retinal tumours. The kidneys, of normal size, showed a large number of white enclosures, metastases also in the supra-renal capsules, in the spleen; no metastases in the uterus or muscles. It was rare that after operation for carcinoma so many metastases were found in nearly all the organs. He had seen similar cases, however, lately, where the disease had been removed early and completely. He had seen one case in private practice and two in hospital. One of the latter was a case of stenosis of the œsophagus in a woman. She had had the left mamma removed about six months before for carcinoma; she now showed dulness on the left side of the chest; after puncture improvement in the stenosis took place, so that she was discharged from the hospital at her own request. In a second case the metastases appeared four months after the operation. One got the impression in such cases that there was some infection. Fifty years ago there was an opinion abroad that carcinoma should not be operated on, as metastases appeared the more quickly, and even when early operation had been performed

In any case, cases such as those just described were remarkable, and gave food for thought.

Hr. Beitzke, who had made the autopsy, said there were no enlarged axillary glands. The way of the metastases was through the supraclavicular glands and from there into the lungs. The vena anonyma had been penetrated on both sides. The recurrent laryngeal nerve was embedded in the metastatic growth, and this caused some hoarseness. There were metastases in the vertebral column, in the femurs, in the bony skull, the thoracic duct, and in the pancreatic duct. The metastases in the brain and eye were of a hæmatogenous nature, and were not directly connected. The ovaries were readily attacked in cases of carcinoma of the stomach, but only rarely so in mammary cancer.

AUSTRIA.

Vienna, Aug. 12th, 1906.

Cardiac Stab Wound Healed.

Hesse recorded a case of wounding of the heart which he treated with perfect success. The lad, who was 13 years of age, received a wound from his comrade on the 8th of June, 1905. The diagnosis was a penetrating wound of the thorax with hæmorrhage. Whether the wound had penetrated the heart or only the mammary and intercostal arteries could not be determined till an opening was made. He was run into hospital fifteen minutes after the accident, and operated on within an hour after admission.

An opening was made in the fourth intercostal space on a level with the stab, from which the blood flowed profusely. After widening the opening, the pericardium was pushed back, which caused an inrush of air to the pleural space. At this stage the direction of the penetrating wound was explored and found to have entered at the cartilaginous end of the fourth rib and passed obliquely towards the heart, running through the pericardium and entering the heart itself. The third rib was sawn, a convex incision made in the pericardium, and the cardiac muscle exposed. There was not a great deal of blood in the pericardium, although a good wide wound was observed in the heart. The stitching of the cardiac wound was a troublesome operation owing to the narrow space and no means of fixing the heart. To obtain perfect drainage a pair of sharp-pointed forceps was passed round the pleural space and another opening made in the thoracic walls below the scapula.

During the first two weeks the course was not without a great deal of anxiety. The first difficulty was a sero-purulent pleuritis with pericarditis, high temperature and a small rapid pulse subsiding about the fifth week. On the 30th of March, or nine months after the operation, the patient was dismissed with an opening in the left side and slight scoliosis in the spine. The heart was now lying to the middle of the sternum, and opposite the space where the portion of rib had been removed. At the base of the heart a dry rubbing synchronising with every pulsation is to be distinctly heard, while the pulse has fallen to 80.

Since his return home no bad effects have presented themselves, but is still unable to do any kind of work. The left lung has greatly improved in function, while the scoliosis has almost disappeared; but there still remains an opening of about two square centimetres, and the pulse 72.

Infantile Mortality.

Dehne next read his report for Leopoldstadt on the death of infants under one year in his department. After stating the condition under which the society took charge of the indigent poor by a note from the poor law officer, he stated that his duty was solely prophylactic, and one which consisted in the admonition of the mother to suckle her own child in spite of all temptation, and for which the society offered a premium. The first instruction for those who could not feed their own child was to use goat's milk.

Where artificial foods were preferred or rendered absolutely necessary, he advised the artificial food to be used with a little weak sterilised cow's milk. After a few remarks on the technique of the prescription. he gave the total number supervised as 869 for 1905 under one year; at the end of the year 370 were under observation. The average attendance was 3·11 months, and the total number of attendances 81,080, or an average number of children to be attended per month 280. Most of the children averaged 4 weeks to 3 months during attendance. The annual consumption of milk was 68,068 litres. Besides this, Szekely and butter milk as well as Liebig soup was ordered. Of the 869 children 439 were fed at breast, with additional milk as age advanced; but 252 were purely breast fed. There were 187 fed on goat's milk entirely, and 243 fed on the artificial food. Putting the partially fed on breast and artificial food together, which is 430, 80 of them died within the year, making 186 per thousand; purely breast fed 17, or 67 per thousand; fed on goat's milk 14 or 75 per thousand, making 111 deaths in the 869 children.

Of these deaths, 27 or 24·3 per cent. died of gastro-intestinal disease, one of them being breast fed, and two from those fed on goat's milk; while 28 or 25 per cent. died from diseases of the air passages. The greatest death rate was in July, 4·5 per cent., August 4·3 per cent. (diarrhœa), November 4·3 per cent., and April, 3·7 per cent. from pneumonia, &c.

BRITISH HEALTH RESORTS.

[FROM OUR OWN CORRESPONDENTS.]

MATLOCK BATH.

Few who have not visited the Peak district of Derbyshire can quite appreciate that there are two Matlocks. Matlock Bath to the uninitiated is Matlock with its baths. Even the express trains of the Midland Railway do something towards the perpetuation of this idea, by running through the little station of the one and stopping at the larger terminus of the other. Yet there is a space of more than a mile between the two towns; Matlock being a large place boasting of several hydros, whereas Matlock Bath can show but one street, no hydros and but one hotel of considerable dimensions. In this connection the question naturally arises, why do medical men send their patients to the latter? The reply to this is, simply for its baths and mineral springs. Matlock has no mineral spring, and the hydros are dependent upon the ordinary town water supply for baths and douches, whereas Matlock Bath has a valuable mineral spring, the water of which is tepid, and almost identical in properties and composition with that of Aix-les-Bains. The little town differs in no way from hundreds of other small communities. It is governed by a district council composed chiefly of small shopkeepers, who are unable or unwilling to take a broad view of their surroundings, or to see that their interests lie beyond the attraction of the tripper, in whose behalf almost every second house has in its windows the familiar announcement of "dinners and teas," and the occupation of its inhabitants would appear to be chiefly diverted to this one channel. To a visitor, especially to one connected with the medical profession, this would appear to be an inexplicable anomaly. Nature has here concentrated her beauties with a lavish hand. Switzerland in miniature, without its snowy peaks it is true, but without the trouble or danger of climbing them. Whether one views the scene from the High Tor above, or midway from the Royal Hotel, or from the Derwent Valley below, it is one of singular beauty, and should attract the well-to-do in great numbers when better known, instead of being handed over as it appears to be wholly to "the tripper." A well known authority once hazarded the opinion that "when Nature had completed Switzerland, there was left one beautiful fragment for which she had no

further use in that country; so she set it in Derbyshire amid a framework of romantic hills, called the Gem of the Peak." This spot is Matlock Bath for which a great future would appear to be assured, notwithstanding the apathy of its district council. Until a few years ago, there was nothing to attract visitors beyond its antiquated baths, and for lack of enterprise the place was regarded as a relic of the past. Much has recently been done to revive its lost popularity, not, be it recorded, by the town authorities, but by the proprietors of the principal hotel through whose grounds the mineral springs run. About two years ago the baths were entirely remodelled, under the direction of Dr. Cecil Sharpe, who has visited most of the Continental Spas, and was enabled to turn to practical purposes the experience thus gained. These baths are placed in the basement of the Royal Hotel, so that patients can descend from their rooms and up again by the lift without the risk of a chill which the separation of spas from hotels elsewhere necessitates. Herein can be had every conceivable form of hydropathic treatment, from the natural mineral water bath of the district, to those of Aix, Vichy and Nauheim of the Continent. But the special feature which is at present attracting the attention of the medical profession, is the treatment of rheumatism, gout, neuritis and kidney disorders by Fango di Battaglia. This substance is imported from Italy, and treatment by it can at present be obtained only at Matlock Bath in this country. It is composed of the volcanic mud thrown up by the hot springs near Padua, and is the origin of the mud baths about which so much has been written. The writer can speak of its effects from practical experience. He visited Matlock Bath with his knee stiff and painful from rheumatism. After half a dozen applications of Fango, the pain and stiffness were gone, and he was able to indulge in lengthy walks with comfort. It may be mentioned also, *en passant*, that the Royal Hotel where the baths are situated is excellently managed and home-like, the sanitary arrangements aothtc, nissud anpie avob patients sent here to undergo "the cure" appear to receive great benefit therefrom. It is, moreover, open all the year round, and as, from the depths of its valleys and the great height of its hills, almost any climatic temperature may be reached, it is well that such a health resort near home should be known.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROFESSORSHIP OF PHYSIOLOGY AT GLASGOW UNIVERSITY.—The King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Diarmid Noël Paton, M.D., to be Regius Professor of Physiology in room of Professor J. G. McKendrick. Dr. Noel Paton was born in 1859, and is a son of the late Sir J. Noël Paton, the well-known artist. He was educated at Edinburgh, Vienna, and Paris, was a Baxter scholar in natural science, and held a biological Fellowship at Edinburgh University. Dr. Paton has for many years been engaged in teaching physiology in the Extra-Mural School in Edinburgh, while his position as superintendent of the laboratory of the Royal College of Physicians has proved his capacity both for carrying out original research and inciting others to do the same. He is well known as a distinguished physiologist, especially through his studies in dietetics, on the functions of the ductless glands; while he has also published a number of valuable researches in connection with the life-history of the salmon. Dr. Paton has ever been a most popular teacher in Edinburgh, and his influence for good and public spiritedness have always made themselves felt in all matters connected with medical education. His training, though in the main physiological, has brought him so much in contact with cliniciens that he has always in teaching emphasised the practical rather than the purely scientific aspect of physiology; he has never forgotten, as some physiologists are apt to do, that their pupils are going to be doctors, not physiologists. Dr. Paton will be greatly missed on his departure from Edinburgh, but all his friends there feel that in him Glasgow has got the right man for the post.

LETTERS TO THE EDITOR.

THE SUPPRESSION OF QUACKERY

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The conviction of the quack, Richard, referred to in your leader of August 8th is, so far, satisfactory, but it must be borne in mind that he was not charged with offences against medical law, not with falsely pretending to be a legally qualified practitioner, and that it will be impossible systematically to cut short the careers of the hundreds of similar rogues until necessary new legislation is provided, together with a public prosecutor not only empowered but obliged to enforce it. The case of the convict Bridgwater, sentenced to penal servitude about a year ago, illustrates the same fact. Under cover of a sham "medical institute" he had been engaged in practice for years, fraudulently pretending to be a "doctor," and carrying on his nefarious schemes unchecked. Thousands of victims had passed through his hands; no attempt to interfere with him had been made, and he might have gone on indefinitely had he not become engaged in the extensive scheme of forgery and fraud which brought him at last within the clutches of the police. I venture to repeat now the assertion which I have made over and over again in your columns, as well as in other medical papers, namely, that it is hopeless to expect any effective and sufficient amendment of medical law to cope with quackery until the public and the legislature shall have become completely enlightened upon the subject. Not only the general public but the great majority of members of both Houses, including all those lawyers who have had no professional experience of the working of medical Acts, are almost entirely ignorant of the evils and abuses at present prevailing. They are quite unable to realise that reform is called for much more for the protection of the public than for the advantage of the profession.

The hideous story of quackery in which is always included the quack medicine trade, needs fully exposing in public. If the story were once and at full length publicly told it would put to shame newspaper proprietors who are now the chief abettors of quackery, and might induce some, if not all, of them to endeavour to make amends by working for the medical law reform so urgently called for. The entire Press, including *The Times*, has so to say bound itself over in opposition to medical reform. The erstwhile leading journal, as you have shown, now derives a large part of its income from quack advertisements of the classes formerly denounced in its editorial columns, and with this example before them it is not to be expected that lower class papers will refuse to augment their incomes by similar means. At present no paper dares to attack quackery, or to give prominence to or comment upon the exposures which are so frequently made in the higher courts of law as well as before coroners and magistrates. The only way by which the whole shameful story can be laid bare lies through the medium of a Royal Commission This I have over and over again urged. I would venture once more to press it upon the attention of the profession. A Royal Commission would have power to call witnesses to examine them on oath and to keep them afterwards free from the danger of prosecution for libel on account of their statements In spite of the political weakness of the profession they could surely obtain the appointment of such a commission if the case were presented and supported by medical M.P.'s and their sympathisers within the House. Commissions on much less important ques-

tions have been appointed within recent years. The case against quackery in every form could be easily proved. Chemical analysis would show the worthlessness of pills, nostrums and panaceas; and the injurious and deadly effects of relying upon them in serious diseases could be demonstrated. The records of the courts supported by a host of skilled witnesses could prove the harmfulness of practice by unqualified pretenders, and it is impossible that the revelations should not touch the consciences of the thoughtful public and of leading statesmen. In obtaining, organising and presenting the evidence, expense would be involved, and this the profession, comparatively poor as it is, could surely afford. There must be many more besides myself who would be willing to contribute to a fund. If a scheme can be started for promoting legislation against medical quackery in every form, the first step to be an agitation for a Royal Commission such as I suggest, I shall be glad to contribute £50 towards a preliminary guarantee fund of £5,000, provided ninety-nine others will put down a like amount or the money be subscribed in lesser sums. The medical profession have always been and are now the chief promoters of all measures for the improvement of the public health and for the protection of the welfare of the people. No greater service could be performed at the present juncture than an attack properly organised upon the gigantic and still growing system of quackery and fraud, the character of which has through past years and lately been so fully exposed in The Medical Press and Circular.—I am, Sir, yours truly,

Henry Sewill.

Cavendish-square, August 9th, 1906.

SENSATIONAL JOURNALISM.

To the Editor of The Medical Press and Circular

Sir,—I enclose a newspaper cutting for your perusal. Is this London hospital recognised by the profession? As a den for charlatans it could not be surpassed for its *charivari*.

What would the Medical Council think of my conduct should I dare to hint at such a practice; yet "respectable professors" descend to the lowest tricks of a mountebank? It is not my object to discuss the blemishes and defects of the Finsen rays, as the results are very enigmatical and questionable if they justify the means. The question occurring to my mind is the morality of such an institution.

"It has more than once happened that people meeting at a hospital ward for treatment have formed attachments and have been married. In some cases these unions are deplorable. For example, two epileptics who attended the out-patients' department of a London hospital got married. After marriage they still attended, and now they bring with them three young children also victims of the disease."

Could anything be more harrowing than this painful revelation that charitable institutions should be the means of bringing such offspring into the world to be maintained by the poor rate? It is surely high time these institutions were closed entirely or put under better control. The London hospital is first advertised as a fine matrimonial centre that the public are very pleased to charitably maintain; that Professor Mountebank performs daily, and that all imbecile offspring are voluntarily supported by the parish and liberally educated at the institution for 'defective children!" Could anything be more absurd or repulsive to a sober mind? Can you tell, Sir, on what grounds this horror can be justified, or how long it must be perpetrated with impunity?—I am, Sir, yours truly,

Nolle Prosequi.

Bootle, August 9th, 1906.

[The cutting of our correspondent is too long to reproduce. It is an extract from *The Daily Mail* of August 9th, and is written in the usual sensational style of that journal. It describes various romances between patients at the London Hospital who suffered from lupus and other unattractive diseases. It is a pity that such stuff should ever "find its way into the papers."—Ed.].

SNOBBERY IN THE ARMY NURSING SERVICE.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been drawn to the comments in your last issue on the above subject. Allow me to verify the remarks which you quote from the *Army and Navy Gazette*. The nurse hunted out was a Miss C., and the lady who carried her case before the Courts a Miss R. The Army Nursing Service under the new Army Nursing Board is purely "class despotism," and that is the why and wherefore of its ranks being under establishment. You urge an inquiry. Catch the authorities giving one, and thus disclosing their own misdoings. The Army nurses are in excess of requirements, and from all quarters a demand for a full and independent inquiry is heard. Snobbery is rife.

I am, Sir, yours truly,

One in the Know.

August 4th, 1906.

OBITUARY.

OSCAR THOMAS WOODS, M.D.

We regret to record the death of this highly-esteemed member of our profession, which took place on August 2nd, at the comparatively early age of fifty-eight. Dr. Woods was son of the late William Woods, Esq., of Parsonstown, and nephew of Dr. Thomas Woods, who died not long ago, full of years and honours, after considerably more than half a century of devoted service to humanity and science in his medical practice at Birr. Dr. Oscar Woods was educated at Trinity College, Dublin, and graduated in arts in 1868, and in medicine in 1869 at the University of Dublin. He adopted the specialty of psychiatry early in his career. He served as Assistant Medical Officer in one or two asylums in England, and it is an extraordinary proof of his amiability that after this long lapse of time he is still remembered with affection by a few surviving patients and colleagues in the institutions where he worked in that country.

In 1875, he was appointed from the Senior Assistancy of the Warwick County Asylum to the post of Resident Medical Superintendent of the Killarney District Asylum, and in 1890 he was promoted to the important charge of the District Asylum, Cork, an office which he occupied till the time of his death. In 1901 his colleagues in his specialty conferred upon him the highest honour in their power by electing him President of the Medico-Psychological Association of Great Britain and Ireland. The annual meeting held that year at Cork under his genial presidency was one of the most successful and agreeable assemblies which that great Society has ever called together.

Dr. Oscar Woods was a most conscientious, high-minded, and hard-working superintendent, interested in every branch of his complex and onerous work, uncomplaining and self-sacrificing in his devotion to his duty. The remarkable progress made at the Killarney Asylum during his rule, and the great reforms effected at Cork after his appointment, attest his high qualities. Lack of time and incessant worry hindered him from writing as much as he otherwise would, but his occasional contributions to medical literature, published in the *Journal of Mental Science* and elsewhere, showed what he could have done under more favourable circumstances. His excellent qualities met the usual appreciation accorded to members of the medical services in his country of late years. He had not the suppleness nor the "policy" required for dealing with public bodies intoxicated with the consciousness of new-found powers. Most undeserved vilification, perpetual "pin-pricking," and incessant annoyance were his lot. The echoes of disputes about his administration were not even stilled around his death bed. The depreciation of health

from which he suffered before the oncome of his fatal and painful illness (cancer of the liver) was probably due in great part to constant worry. He suffered also under poignant family trouble. His second son, a lad of much promise, died after a brief illness, and his eldest and favourite daughter soon followed. These repeated blows told heavily upon him. He was a man to whom the buffet of fortune seemed specially unjust, for he was of an affectionate disposition, perfectly straightforward, full of blunt good-nature, and incapable of unkindness or double dealing.

Dr. Woods leaves a widow and six children to mourn his loss. He will be regretted by everyone in his own specialty, and by all the members of his profession who had the advantage of knowing him.

DR. G. B. FRASER, WESTON-SUPER-MARE.

WE regret to announce the death of Dr. G. B. Fraser, of Weston-super-Mare, on August 8th. On the day that he was taken ill (July 9th) Dr. Fraser gave evidence at an inquest, and later performed an operation. An hour or so afterwards he was seized with severe illness, and took to his bed. Dr. Fraser had practised in Weston-super-Mare for many years. He was fifty-four years of age. Of a most genial disposition, the doctor was generally beloved, and his goodness of heart was manifested by the devoted services he rendered to the Royal West of England Sanatorium and Children's Convalescent Home as honorary medical officer. For some years he held rank in the Devon and Somerset Volunteer Engineers, and only a fortnight ago he was granted the honorary rank of Surgeon-Colonel, on resigning his commission, with permission to retain his rank and wear the prescribed uniform. Dr. Fraser was the second son of Mr. Peter Gordon Fraser, some time Colonial Secretary of Tasmania, where he was born. He was educated in England, and after a successful medical training he obtained his professional degrees, and was appointed house surgeon at St. Mary's Hospital, London. Subsequently he succeeded to the practice in Weston-super-Mare of the late Dr. Julius Wilmott. During his long residence in Weston-super-Mare he won the respect of all classes, his sympathetic nature endearing him to all, especially the children.

DEPUTY SURGEON-GENERAL H. F. SMITH, M.D. ABER., M.R.C.S.

DEPUTY SURGEON-GENERAL H. F. SMITH, late of the Army Medical Department, died on Sunday, the 5th inst., at Graitney Hall, at the age of 82. Qualifying as a member of the Royal College of Surgeons, England, in 1846, he joined the Army as an assistant surgeon in March, 1847, and having taken the M.D. degree at Aberdeen in 1850, served throughout the Eastern campaign of 1854-55. He had medical charge of the staff belonging to the Adjutant and Quartermaster-General's Departments, and was subsequently on the personal staff of Sir James Simpson and Sir William Codrington. He was present at the action of Bulganac, at the battles of the Alma, Balaclava, and Inkerman, and throughout the siege of Sebastopol till the fall of the fortress, receiving for his services the medal with four clasps, the Turkish medal, and the Fifth Class of the Medjidie. In 1859 Dr. Smith was admitted a member of the Royal College of Physicians, London, and in March, 1867, was promoted surgeon-major. He retired in 1875 with the rank of deputy surgeon-general.

JOHN HUDSON, M.D.LOND.

DR. JOHN HUDSON died on Monday, the 6th inst., at his residence in Cork Street, Burlington Gardens, in his eighty-eighth year. Dr. Hudson, who had long retired from practice, was professionally educated at Leeds and in London, and qualified as a member of the Royal College of Surgeons, England, and a licentiate of the Society of Apothecaries in 1841, taking the M.B. degree at London University in 1842, and the M.D. in 1846. Dr. Hudson was for a considerable period resident medical officer to the "Dreadnought" hospital ship.

DR. F. B. O'FLAHERTY.

THE death of Dr. F. B. O'Flaherty, of Liverpool, took place on Wednesday, at the residence of his uncle, Dr. Brannigan, 109, Upper Parliament Street, at the age of 45. Dr. O'Flaherty, who practised in Park Road and neighbourhood, was one of several brothers. The interment took place in Flaybrick Hill Cemetry, Birkenhead, on August 3rd, at noon.

LITERARY NOTES.

THOSE interested in voice-production will find yet another system propounded in "A New Method of Respiratory Vocal Re-Education," written by F. Matthias Alexander, and published by Messrs. Bailliére, Tindall and Cox. It is perhaps hardly fair to criticise the pamphlet, as the author aims only at giving his readers an introduction to his methods, and promises fuller details later. At any rate, Mr. Alexander points out some common errors in voice production, and if his system can teach people so to re-educate their respiratory mechanism as not to fall into them, he will have something substantial in his favour.

***

"The Levantine Riviera, Italy," by W. T. Beeby M.D., will give its readers a glimpse into a region which is at present undreamt of in their philosophy. And a charming region it is, too, we judge from the description. Not that Dr. Beeby puts the butter on "thick," for he writes with commendable restraint, but because the historical associations and natural beauties of the Levantine Riviera combine to make it an unusually attractive winter resort.

***

Two simple little pamphlets dealing with early training in a popular fashion are "How to Live," by Richard Caton, M.D., F.R.C.P., J.P., and "Baby," by Edith L. Maynard.

***

THE former aims at being a primer for pupils in elementary schools, discovering to them the principles of healthy living; whilst "Baby" tells the poorer classes of mothers how to treat their infants. Although we might have written them differently ourselves we can say that they both fulfil their humble but necessary functions fairly well.

***

"Public Health Acts and Other Sanitary Laws and Regulations," by Martin Elliott, Barrister-at-Law, and Gilbert Elliott, M.R.C.S., L.R.C.P., D.P.H. (H. K. Lewis), seeks to give a concise *résumé* of the sanitary laws as they stand at present. Being little else than an abstract, it does not call for much in the way of comment, though it may be found of value by students working for the Diploma in Public Health. It is curious that the authors should speak of "my brother Gilbert Elliott" in a preface signed by them both, and even more so that the Public Health (London) Act should be passed over in silence.

THE Duke of Northumberland is taking an active interest in the arrangements connected with the second International Congress of the Association for the Promotion of Hygiene and Salubrity in Dwellings, to be held at Geneva from September 4th to 10th. Representatives from all the countries of Europe, the United States, and Canada will attend. Dr. Vincent, State Councillor of the Canton of Geneva, will be the president of the Congress.

THE P. and O.'s mail steamer "Arabia," on her arrival at Plymouth on Saturday, reported a case of plague on board. The patient, a Lascar seaman, has been isolated, and the passengers and crew medically examined.

SPECIAL ARTICLES.

JAPANESE MEDICAL HEROES.

It is certain that Japan will in no distant future take a foremost place in the ranks of scientific medical progress. So far as military surgery is concerned, Japan has already secured a position second to none. The records of Japanese army work during the recent war stand *facile princeps* in the annals of history.

Dr. Umeno.

Dr. Shigo

Dr Sakarnote.

Under these circumstances it is interesting to know anything personally about the men who are making this particular kind of history in Japan. We have much pleasure in reproducing from a recent copy of the *Tokio Graphic* the portraits of three distinguished natives of Japan. They are Dr. Shigo, decorated by the Emperor for his discovery of the dysentery bacillus. Dr. Umeno, who obtained a similar honour in recognition of his research work in vaccines, and Dr. Sakarnote, whose distinction was granted because of his invention of the electric vitascope.

LABORATORY NOTES.

STERILISED VAGINAL SUPPOSITORIES.

We have received from Messrs. Parke, Davis & Co. two vaginal suppositories that should be of much value to the general practitioner who is called upon to attend midwifery cases. They are of two kinds, as suggested by Dr. W. P. Manton: No. 1—Contains five grains of iodoform each; No. 2—Contains five grains of boric acid and three grains of aristol each. They are intended for post-partum use, both as checks to microbic development, and for healing lacerations of the cervix or perinæum. By this means a sustained local effect is obtained, which is likely to be more productive of good results than simple vaginal douches. In the preparation of these suppositories the utmost care is taken to ensure asepsis. The ingredients, wrappers and the operatives' hands are, we are informed, scrupulously sterilised before the work is commenced. These suppositories are packed in sterilised tubes and furnish medical men with a handy and trustworthy means of securing asepsis after delivery.

ETHOL SOAP.

Messrs. Parke, Davis & Co. have sent us samples of a new fluid soap which possesses a remarkable affinity for grease. It is free from strong alkalies or anything that could injure the skin, yet exerts a strong solvent action on oil and fat, and is consequently a great boon to motorists, cyclists and amateur machinists, who are liable to get their hands soiled with greasy dirt. A little is poured into the palm and worked over the hands, water is then added and a lather raised in the usual way. On rinsing with water it will be found that the grease has been effectually removed.

Ethol is supplied in metal screw-cap flasks of two sizes, the smaller being particularly suitable for carrying in the pocket.

The same firm have also prepared a granular effervescent laxative lithia. The preparation is composed of pure ingredients, and when dissolved liberates a large amount of carbonic anhydride which provides a sparkling and agreeable draught. Each teaspoonful contains 5 grains of lithium citrate and 30 grains each of potassium citrate and sodium phosphate. The laxative principles are present in quantity sufficient for ordinary requirements. These granules are supplied in bottles of 2 ounces and 4 ounces, and we can testify personally to their excellence.

Another preparation of the same drug is in the form of effervescent lithium citrate tablets. Each contains 5 grains of lithium citrate. They disintegrate readily in water with brisk effervescence, forming a pleasant draught.

EUMENTHOL TOOTH POWDER.

There is always, commercially speaking, room for a good tooth powder, which in this case has come to us from the Antipodes. Under the name Eumenthol an excellent tooth powder has been produced by Mr. G. Hudson, a well-known chemist, of Ipswich, Australia. The powder is rose pink, finely divided, with a delicate aromatic odour, and in practice will be found to answer its purpose perfectly. We have previously had the pleasure of noticing other preparations of Mr. Hudson's in these columns. The Eumenthol powder is put up in a well-made and convenient metal bottle, with an ingenious device for shaking out the powder.

MEDICAL NEWS IN BRIEF.

The International Anti-Tuberculosis Association.

MANY important practical questions relating to the campaign against tuberculosis are on the programme for discussion at the International Tuberculosis Conference to be held at The Hague, September 6th to 8th. Amongst the speakers will be the following:—On ways of infection—Calmette (Lille), Flich (Philadelphia), Spronck (Utrecht); on specific therapeutics—Brown (Saranac Lake), Maragliano (Genoa); on compulsory notification—Biggs (New York), von Glasenapp (Berlin), Holmboe (Christiania), Raw (Liverpool); on cost of sanatoria—Klebs (Chicago), Lorentzen (Copenhagen), Pannwitz (Berlin), Schmid (Bern), Walsh (Philadelphia); on dispensaries—Dewez (Mons), Kayserling (Berlin), Philip (Edinburgh); on tuberculosis in children—Dietrich (Berlin), Léon Petit (Paris), Schlossmann (Dresden); on education—Heron (London), Pannwitz (Berlin).

The Special Report by the Lunacy Commissioners on Insanity in Ireland.

THIS report, for which the medical profession and the public have waited for a considerable time, has at last been laid before Parliament. It has not, however, as yet been issued to the public in its complete form, and therefore we are only in a position to place before our readers a short summary of the conclusions reached by the inspectors. These are as follows:—

(1) The census statistics of a number of decades past show that while the population of Ireland has continued to decrease, the number of the registered insane has largely increased, and this has given rise to a widespread belief that an actual increase of occurring insanity has taken place in Ireland. Whether or not this belief is well founded it is impossible to state positively, as the available statistics do not afford that precise information on which a definite conclusion can be based. (2) Without venturing to affirm that there has been no increase of occurring insanity, so far as the information at our disposal enables us to form an opinion, we can only conclude that the very great increase which has taken place in the ratio of insanity to the population, is largely due to the accumulation which is taking place in the public asylums; partly to reduction of the population by emigration, and partly to the return of emigrants suffering from mental breakdown, who have either come back voluntarily or have been repatriated by the United States Government. The emigration of the strong and healthy members of the community not alone increases the ratio of the insane who are left behind to the general population, but also lowers the general standard of mental and bodily health by eliminating many of the members of the community who are best fitted to survive and propagate the race. (3) The increase in numbers has taken place mainly amongst the insane supported out of the public rates—the increase amongst the classes who are able to pay, or whose relatives are able to pay for their maintenance in private institutions being small in comparison. (4) The increase of the actual numbers in asylums is principally due:—(*a*) To accumulation, caused by the low and decreasing discharge and death-rates—the latter being much lower than the corresponding rates in England and Wales. (*b*) To gradual absorption into asylums and workhouses of the unregistered insane. (*c*) To the widening of medical opinion as to the degree of insanity which justifies certification and transfer to institutional care. (*d*) To the greater confidence on the part of the poorer classes in the methods of treating the insane in asylums. (*e*) To the increase in the number of asylums, and their greater accessibility. (*f*) To the greater longevity of the population generally, owing to the progress of sanitation. (*g*) To the influx of returned emigrants, who, having broken down mentally abroad, return or are sent back to this country to swell the numbers of the insane. (5) The statistics of insanity in other countries, even more than those of Ireland itself, point to the fact that the Celtic race, notwithstanding their undoubted intellectual gifts, are peculiarly prone to mental disease. (6) While the statistics dealing with the exciting causes of insanity do not exhibit any marked variation from those shown in former reports, it cannot be too prominently pointed out that—next to heredity, which is itself in some cases the direct result of alcoholic excess in the progenitor—intemperance in the use of alcohol continues to head the list. The statistics also show that general paralysis of the insane—a disease at one time almost unknown in Ireland—is now increasing in the more populous urban districts.

We hope to deal with the full report at a later date.

French Mission to West Africa.

THE Paris Society of Geography, under the presidency of M. le Myre de Villers, are organising a French mission to West Africa to study the disease of sleeping sickness. A sum of 200,000f. (£8,000) has already been collected. In addition to the generosity of the members of the Society, notably Prince Roland Bonaparte and Dr. Girard, important contributions have been received from leading French banks, from French houses interested in West African trade, and even from two British commercial houses in French territory. For the choice of the *personnel* of the mission the Pasteur Institute was appealed to. Dr. Roux selected a young officer of the French Medical Corps, Major Martin, who had worked at Saigon and at Lille in the Pasteur Institutes, and had already had an opportunity in Guinea of studying sleeping sickness. He is to be assisted by Dr. Lebeuf, whose scientific attainments have been put to the test in the Congo, by M. Roubaud, a graduate of the Museum, and by a young naturalist, M. Weiss, who has spent some years in Tunis. The mission is to leave Paris in October for Brazzaville, where it will recruit among the natives its interpreters and hospital attendants. After establishing a permanent central laboratory the mission will begin the direct study of the malady up country. Special attention will be paid to the Upper Ugandi region.

Doctor's Action.

AT Leeds Assizes, on August 11th, Mr. Justice Grantham delivered judgment in an action brought by Dr. E. S. Steward, a Harrogate physician, who claimed £130 from a gentleman of the same town, Mr. Alexander C. Weir. The parties were formerly fast friends, and according to counsel, the mining transactions between them were curious and complicated. The defendant had been engaged in company promoting, and lived in good style at Harrogate. The defendant said that he knew of a very excellent investment, and, as a great favour, he would let plaintiff have some shares which would yield a very considerable profit. The plaintiff took a hundred fully-paid shares in the "Anglo-Transvaal Mines (Limited)," which were to be pooled. The plaintiff, however, could get no scrip recording the transfer, and the defendant denied the contract to deliver the shares. A witness said that the pooling managers did not think themselves justified in selling the shares until they had some information they were seeking to obtain. The defendant, in his evidence, said he explained the pooling arrangement to the plaintiff

several times. The arrangement was that the shares were not to be sold for under 30s, before April 1st. Mr. Justice Grantham gave judgment for the plaintiff for the full amount claimed, and costs. He said that the defendant had purported to sell an article which had no existence, and there had, therefore, been a total failure of consideration for the payment of the £130. The plaintiff must have a verdict. A stay of execution was refused.

Plague Precautions in Mysore.

At the present moment a systematic campaign of rat destruction is being carried on in Mysore under the express orders of Mr. Madhava Rao, the Minister of that State. Colonel Smyth, the Sanitary Commissioner, has directed in person the operations in Mysore City, which is the place of residence of the Maharajah. The people have manifested a welcome desire to aid the authorities, as they are now convinced of the close connection between rats and plague. The members of the Jain sects who are opposed to the taking of life in any form, are alone retarding the measures now in course of execution; but it is hoped that the influence of Mr. Madhava Rao will avail to overcome their objections, so far, at least, as to induce them to remain passive while their houses are purged of vermin.

Friendly Societies.

On July 27th, the Clay Cross and District Friendly Societies' Council listened to an interesting and instructive address on "Medical Associations," given by Mr. Bradwell (editor of the *Equalised Order of Druids' Magazine*), of Sheffield. Dealing exhaustively with the subject, he first of all gave caution against certain errors in the formation of such societies, and care in forming such associations. It had been stated that three grades of drugs were used by the medical men: First, for private patients; second, for club members; and third, for those dependent entirely on the parish. By medical associations the club members received only first-class medicines, and none other were allowed to be purchased; the firms supplying drugs having to warrant them as the best on the market. The result was that members were speedily restored to health, especially as, coupled with pure medicine, was the thorough and entire attention of the doctor. The courts and lodges benefited materially, as the funds were thus saved. Medical societies provided also for members' wives and children at reasonable rates, and thus obviated what in large towns was severely felt by the poorer classes—the inability to pay at ordinary rate for medical service. He said it had been stated that only poorly-qualified men could be induced to serve such associations. That was absolutely false. In Sheffield the two gentlemen who served their association were each an M.R.C.S., L.R.C.P., and one of them had also other special qualifications. They might rely upon it that when they were ready for them they would be able to obtain gentlemen who would serve them honourably and successfully. The financial difficulties were by no means great, and the prospects of increase in number and magnitude of such societies were very bright.

Midwife Sentenced.

Ann Taylor (64), midwife, was indicted on a charge of having, at St. Helens, on June 9th, feloniously killed and slain Ruth Dinah Gibson. Mr. Lias prosecuted, and Mr. H. L. Riley defended. The evidence for the prosecution was that the deceased was the wife of James Gibson, a collier, and that the prisoner was a certificated midwife. The prisoner attended the deceased on her premature confinement. Twins were born, and both died two days later. It was alleged that the prisoner should have sent for a medical man and waited until his arrival, but this she failed to do. It was also alleged that she was under the influence of drink, that she unskilfully performed a delicate and dangerous operation on the deceased, which ought to have been done by a surgeon, and that she ceased attendance on the deceased earlier than was allowed by the regulations. Mrs. Gibson's death was due to septic poisoning, which was found upon a *post-mortem* examination to have been due to improper attention. The witnesses for the prosecution included Dr. Buchan, Medical Officer of Health for St. Helens.

The prisoner, giving evidence on her own behalf, said she was a widow, and had been a midwife for thirty-four years. Mrs. Gibson was the only patient that had died under her treatment, and there had been previously no complaint against her. She denied having been under the influence of drink at the time in question; she had not had any drink for about twelve months. She also denied having treated deceased improperly. She twice advised the deceased to get a doctor. Questioned by the judge, the prisoner said at first that she had a clinical thermometer, but afterwards admitted that she did not know what a clinical thermometer was. What she meant was a smal bottle of disinfectant.

The jury found the prisoner guilty, and strongly recommended her to mercy on account of her age. His lordship said he would bear in mind the prisoner's age, the fact that she was a relic of an old system, and other favourable circumstances. She must go to prison for three months in the second division.

Germany and Tuberculosis.

From 1901 to 1905 the insurance companies of Germany have expended nearly £2,000,000 in fighting the scourge. This outlay included twenty-six sanatoria, with 2,111 beds, for women, and ten sanatoria, with 541 beds; for children, all these being due to the suggestion of the German Empress.

Illness in Camp.

Some alarm has been occasioned in the military camp at Fleetwood by the sudden outbreak of a mild form of typhoid among the officers of the 3rd North Lancashire. The cause of the outbreak has not been ascertained yet, but a strict investigation is being conducted by Captain Rodgers and Major Pearce, of the Royal Army Medical Corps, who have been sent down from Chester. Bacteriological examinations of food and of the water supply are being carried on, and the evidence, it is stated, points to the latter being contaminated in some way. In consequence of the sickness the officers' mess has been closed.

List of Mortality.

According to the Registrar-General's Report for the week ending August 4th, the deaths registered last week in seventy-six great towns of England and Wales corresponded to an annual rate of 13·8 per 1,000 of their aggregate population, which is estimated at 15,818,360 persons in the middle of this year. In the preceding three weeks the rates had been 11·7, 12·0, and 12·6. Table 1 of this return shows, for the several towns, the death-rates in each of the last four weeks; it also shows for the week ended last Saturday the births, the deaths from several causes, and the death-rates from certain epidemic diseases. Measured by last week's mortality, the highest annual death-rates per 1,000 living were:—From all causes, 19·0 in Newport (Mon), 19·7 in South Shields, 19·8 in Stockton-on-Tees, 20·3 in Rochdale, 20·5 in Wigan, 21·2 in Coventry, 21·4 in Huddersfield, and 26·9 in Bootle; from measles, 2·0 in Salford, 2·5 in Burnley, and 3·8 in Huddersfield; from whooping-cough, 1·3 in Portsmouth and in Birkenhead; and from diarrhœa, 3·0 in Leeds, 3·1 in Birkenhead, 3·3 in Walsall, 3·5 in West Ham and in Merthyr Tydfil, 4·2 in Wigan, 4·4 in Leyton and in Aston Manor, and 5·5. in Bootle. No death from small-pox was registered in any of the seventy-six towns. In London 2,576 births and 1,272 deaths were registered. Allowing for increase of population, the births were 22 above and the deaths 12 below the average numbers in the corresponding weeks of the previous four years. The annual death-rate from all causes, which had been 11·8, 11·6, and 11·7 per 1,000 in the preceding three weeks, rose last week to 14·0. The death-rate in the four weeks ended last Saturday averaged 12·3 per 1,000, being 1·9 per 1,000 below the mean rate in the corresponding periods of the four years, 1902-5.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Alcoholic Dextrins and Marasmus.—Symes (*Brit. Journ. of Children's Diseases*, July, 1906) discusses the value of alcoholic dextrins, given in the form of Guinness's stout, in the treatment of some severe forms of marasmus in children. Symes has found that in a certain proportion of children a condition of marasmus develops as a result of the early administration of improper food, which defies all methods of artificial feeding. He illustrates three such cases in which various artificial foods, as well as modifications of cows and asses' milk, were tried but still the child continued to vomit, and decline in weight. In each of these cases the addition of porter to the child's food was followed by a marked and steady improvement in weight and in the general condition of the little patient. Approximately 1 oz. of stout is equivalent in alcoholic value to 1 dr. of brandy, and half an ounce can be given to a marasmic infant every four hours with the greatest safety. Symes orders the stout in the following way: Guinness' XXX stout ½ oz., hot water ½ oz., cream ½ to 1 dr., fresh beef juice 2 to 3 dr., sugar—every four hours. In no case in which the stout was used did it intoxicate the child or make him drowsy, and no hiccough, flatulence or diarrhœa was observed. The stout itself may be described as an extract of malt containing abundant carbohydrates in the form of dextrins, no starch, no sugar, and a small quantity of alcohol averaging about five per cent.

Enteric Fever with Spontaneous Rupture of the Spleen.—West and Dudding (*The R.A.M.C. Journ.*, Aug., 1906), describe a case in which the death of the patient resulted from this rare complication. On admission to hospital the patient complained of having been ill for two days, his temperature was 101·4° F., there were no rose spots on the abdomen and no marked enlargement of the spleen was observed. Four days after admission to hospital rose spots were first seen, but even then the splenic dulness was not marked. Three days later he complained of sudden and severe pain in the abdomen and vomited. He rapidly became very collapsed, somewhat restless, with weak and rapid pulse, and the abdomen was tender, distended and tympanitic, and the liver dulness diminished. Perforation of the intestine being diagnosed, the patient's abdomen was opened three hours later. The lower part of the abdomen was found to be filled with blood by which the intestines were floated up against the anterior abdominal wall, but there was no air in the abdominal cavity. Careful search was made for perforation of the intestine, but none was found and the patient's condition was so bad that the abdomen was closed, the cavity having been washed out with very hot saline solution. The man died shortly after. On *post mortem* examination the spleen was found to be very large and to have a rupture about three inches long on the diaphragmatic surface, the capsule being extensively separated by blood clot. Well-marked enteric ulcers were found in the intestine, and the mesenteric glands were enlarged. The other organs were healthy. K

The Practical Significance of a Trace of Albumen in the Urine.—Tunis (*The American Journ. of the Med. Sciences*, July, 1906) discusses this important question, and reviews the opinions expressed upon it by a number of representative physicians. "By a trace of albumen is meant such a trace of albuminoid substance as can be detected by means of the heat and nitric acid test or by Roberts' solution properly applied—such a trace not to be accompanied by any tube casts of pathological significance *per se* in an otherwise perfectly healthy man." Tunis quotes the views of various writers on this subject and finds in them little or no agreement. In order to secure a consensus of present day opinions, a letter asking the following questions was sent to about twenty representative physicians: (1) Is there such a condition as physiological albuminuria? (2) Have you had under your observation any case or cases where a trace of albumen has been present in the urine for ten years or longer in an apparently healthy man? (3) Do you not think that the mortality among cases showing continuously a trace of albumen is much greater than among an equal number of healthy lives during the same period? The answers received varied a good deal, but that to the third question was in the affirmative in all but two instances. From the evidence at his disposal Tunis draws the following conclusions: (1) From any point of view the term "physiological albuminuria" is almost universally regarded as misleading, unsatisfactory, and inadequate. (2) As long as albumen is a constituent of the urine the individual voiding it cannot be regarded as normal. (3) The mortality among such persons must necessarily be higher than among an equal number of individuals who do not show this phenomenon. (4) The actual mortality rate among this class can best be approximated by a comparison of the records of half-a-dozen of the largest life insurance companies (dealing with hundreds of thousands of cases) over a period of twenty years at the least. (5) The prompt means of discriminating between the transient forms of albuminuria and those of real clinical significance may be found in some such therapeutic test as that of calcium lactate, rather than by any further developments in the chemistry of the urine. (6) Experience proves that "a faint trace of albumen" is often of greater significance than "a decided trace" by unexpectedly directing attention to the finding of casts of pathological importance, which might otherwise have been easily overlooked. (7) For practical purposes the heat and nitric acid test for albumen is the best one, and the careful use of Roberts' solution the most satisfactory control test in doubtful cases. (8) For the proper diagnosis and prognosis too much stress cannot be laid on a thorough consideration of the clinical conditions as a whole. K.

Cancrum Oris.—Telford (*The Med. Chronicle*, July, 1906) describes a severe case of this disease in a child æt. 7. Besides the usual surgical treatment of free excision of the diseased parts and swabbing with pure carbolic acid, the child was given considerable doses of antidiphtheritic serum. The diphtheria bacillus does not appear to have been isolated from the patient, but the nurse who attended the case fell sick with an acutely injected throat from which, by culture, the diphtheria bacillus was obtained. The child made an excellent recovery, and was discharged from the hospital ten days after admission. K.

"Memorandum" Regarding Antityphoid Inoculation.—Captain Harrison (*Journ. R.A.M.C.*, July, 1906) points out that the vaccine now in use is modified in accordance with experiments made during the last year and a half. The dose which is recommended at present is a quantity containing 500 million bacteria for the first dose and a 1,000 million for the second dose. These are generally contained in 1 cc. and 2 cc. of fluid respectively (18 and 36 minims). This vaccine was used for the 17th Lancers, and the results of the epidemic among this regiment at Meerut have all the force of a

laboratory experiment, since the men who formed the test were all under the same conditions throughout. The only case among the inoculated men in the Meerut epidemic occurred in a man who had refused the second dose. The clinical effects of the inoculation are much milder than was the case with the old vaccine, As a rule, all symptoms have disappeared thirty hours after inoculation. After the second dose the local reaction comes on, and disappears more quickly than after the first, and as a rule there is but little general reaction with the second dose. Re-inoculation is advised once in two years. K.

Meniere's Disease and Meniere's Sympton.—Amberg (*American Journ. Med. Sciences*, July, 1906) discusses the advisability of giving up this nomenclature in the description of ear diseases. Amberg considers that the triad, hardness of hearing, vertigo and tinnitus which constitute the functional disturbances observed in the so-called Meniere's disease also occur in numerous affections which are not based on the pathological finding as described by Meniere in his historical case. The introduction of a more definite nomenclature would be of importance from a physiological, a pathological and a clinical standpoint and would be in accordance with the procedure in other departments of medicine. K.

Leubartz Treatment of Gastric Ulcer.——Haberman (*Med. Record*, New York, June 16th, 1906) gives the following treatment of gastric ulcer: Absolute rest in bed for at least four weeks; avoidance of all mental excitement; the almost continual use of an icebag over the stomach for two weeks; the administration of between 200 and 300 cc., of iced milk, given in spoonsful, and from two to four beaten eggs; the administration for ten days of 2 grs. of Bismuth subnit. at a dose. The eggs are beaten up entire, with a little sugar, and the dish containing them is placed in a receptacle filled with ice; sometimes a little wine is added. This food at once binds the supersecretive acid, mitigates the pain, and causes the vomiting to cease. After a few days some raw chopped meat is given. In the third week quite a mixed diet is allowable. D.

Case of Veronal Poisoning.—Germann (*Journ. Amer. Assoc.*, June 30th, 1906) records a case of veronal poisoning in a young, healthy man, æt 22, who took 200 grains of the drug. The following points were noted: Persistent coma for seventy-nine hours, pulse remained quiet and steady till very near the end; gradual rise of temperature to 108·4 *ante mortem*; cyanosis appeared only very late. *Post mortem* was found intense cerebral congestion and marked congestion of organs, especially the stomach. D.

Mercurial Treatment by Way of the Rectum.—Audry (*Annales de Dermatol et de Typh.*, Paris, 1906), has given this method of mercurial treatment thorough trial in forty-eight cases, and has been much pleased with the results. He gives the details of thirty typical cases, all showing that mercurial medication by way of the rectum is perfectly tolerated and is as effectual as by other technics. He administers the mercury in the form of suppositories made of cocoa butter, and a liquid preparation of metallic mercury in olive oil and vaseline; each suppository contains 2 cc. of mercury. One suppository is used every evening for a month; they are then omitted for four or five days, and then again given. One child of 3 was thus treated with 100 suppositories during four months, each suppository representing 1·5 cc. of mercury. No local or general inconveniences of any kind were observed. The effect seems to be the same as from other methods of mercurial treatment. In some control cases the course of the lesions under this and parallel mercurial treatment by the ordinary technics seemed to be identical. The action of the rectal medication was particularly prompt and certain in case of lesions in the anogenital region and in the mouth and throat. D.

Enterogenic Cyanosis.—Van der den Bergh and Gruterinck (*Indian Med. Record*, June 13th, 1906), describe six cases of cyanosis dependent on the absorption of toxic products from the intestine. The cases could be divided into two distinct types. In one set the blood gave the spectrum and chemical properties of salphohæmoglobin, while in the other genuine methæmoglobinemia was present. In the cases of the former class the condition was promptly relieved by a thorough course of intestinal purgation, and in the other the cyanosis would disappear after one or two days of rigid milk diet, to return again when vegetables were added to the regimen. After considerable time had been spent in experimentation, it was discovered that the cause of the reduction of the hæmoglobin was the presence in the blood of nitrites, probably dependent on their increased production in the diseased intestinal canal. D.

Diphtheria Antitoxin in Chorea.—Hamilton (*Med. Record*, New York, June 16th, 1906) saw a case of chorea in a boy, æt. 15, who had suffered from an aggravated form of chorea for several months. He gave the boy full doses of antitoxin, after which the chorea symptoms disappeared and did not return. Recently he attended a young man who suffered from chorea following rheumatism. Delirium developed into a violent mania, and it was plain that unless relief was afforded, death was not far distant. Three thousand units of diphtheritic antitoxin were administered, after which the chroreic symptoms were so much relieved that all restraint was removed. After two more doses, the first of 1,500 and the second of 2,000 units of antitoxin, all irregluar muscular symptoms subsided and have not yet returned. D.

Picric Acid Poisoning.—E. J. Eliot (*Lancet*, April 28th) calls attention to an important case of picric acid poisoning, which occurred in a girl of 14, burnt about both arms, second and third degree, who was treated by the application of a saturated solution of picric acid to the raw surface every second day. All went well for seven days, when the symptoms of poisoning first showed themselves. They were:—(1) Intense sickness, tongue dry and furred; (2) temperature, previously normal, rose to 102, pulse to 154; (3) conjunctiva became yellow and skin generally showed an icteric tint; (4) a bright red papular rash over almost the entire body; (5) the urine bright red in colour, with a greenish shimmer on the surface. The application of the picric acid was stopped and at once all these symptoms disappeared. In most of the recorded cases of picric acid poisoning, all the above symptoms have been present, but in several cases diarrhœa also occurred. The rash may easily be mistaken for measles, but it spared the face, and was especially well marked in those parts of the body in contact with each other, and also where subjected to pressure. G.

The Staining of Blood Platelets.—So varying are the results, even with the best blood-stains, in the appearance of blood-platelets, that many observers fail to distinguish platelets from artefacts. A trustworthy method of staining them opens up, therefore, almost a new field of study. Wright (*Boston Med. and Surg. Journal*, July 12th, 1906) recommends a method by which he claims to have obtained excellent results. Perfectly fresh tissue, *e.g.*, the spleen of a young kitten, should be fixed in methyl alcohol, dehydrated by acetone, cleared by xylol, and imbedded in paraffin. Sections should then be cut, and stained by Wright's method for blood smears. The method is as follows: Cover the film or section with Wright's fluid and add an equal quantity of water; after ten minutes rinse in water; dip in 1 in 5,000 solution of sodium hydrate for five seconds; wash in water; dehydrate with acetone; clear with oil of turpentine; mount in turpentine colophonium. Wright regards the acetone and turpentine as essential to the process, as he knows no other dehydrating and clearing agents which do not destroy the characteristic staining of the platelets. R.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

F. (Bakewell).—By the Factory Act an injured workman cannot be compelled to submit to a suggested treatment prior to the final assessment of the compensation due to him as the result of the accident. Had your patient allowed an operation, and died from it, the employer might have repudiated all liability.

A SKELETON ODE.

O skeleton within the big show window!
How oft I envy you your bony quiet!
You've no more aches or pains or worries,
And now you never have to watch your diet.

"Neuralagy" never tries to reach you;
The rage of "rheumatiz" you no more feel;
You're never scared by reading of the microbes,
And you've no fear of any surgeon's steel.

—*The Doctor*, America.

M.D.—(Tonbridge).—There is a sanatorium exclusively for ladies at Ebersteinburg, half-an-hour from Baden-Baden. We think a Dr. Rumpf is at the head of it.

POPULAR IDEAS.

OVERHEARD IN THE STREET.

OLD WOMAN: "I persuaded my man to go to the vet.; 'e's a nice old gent."

FRIEND: "Why didn't he go to the young man at the 'Spensary?"

OLD WOMAN: "'Cos, as I said, an ole vet.'s better'n a young doctor, any day."

LECTURER.—Certainly the course of lectures should be useful. There are so many ambulance members who carry directions in their pockets and not in their heads. Only this week we saw a policeman forcing an epileptic into a sitting posture and trying to pour brandy down her throat.

EPHIDROSIS.—The advice given in popular papers of the type you quote is beneath contempt as a rule. But it is interesting to notice that of late years the ideas of the writers are a little less crude than they were. The suggestion "Not to mingle with crowds when overtired" as a suggestion for avoiding pneumonia is, as you remark, characteristic of this kind of writing.

BARON MUNCHAUSEN AND THE COLLEGE OF PHYSICIANS.

WE quote the following from the orginal edition of "The Travels of Baron Munchausen" for comparison with the edition in the possession of a Liverpool correspondent referred to in our last:—"On the 30th Sept., when the College of Physicians chose their annual officers and dined sumptuously together, I filled my balloon, brought it over the dome of their building, clapped the sling round the golden ball at the top, fastening the other end of it to the balloon, and immediately ascended with the whole college to an immense height, where I kept them upwards of three months. You will naturally inquire what they did for such a length of time? To this I answer, had I kept them suspended twice the time, they would have experienced no inconvenience on that account, so amply, or rather extravagantly, had they spread their table for that day's feasting."

DR. H. (Leeds).—Thank you for MS. sent in, but it is a little one-sided. There are many provisions made for the safety and health of employés which are never used by them. A large manufacturer said the other day he constantly had to put up "fool protectors," owing to the deliberate carelessness of his men.

LONDON M.D.—We would strongly dissuade you from going either to Johannesburg or Durban. There is no lack of doctors there, but only lack of money.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 15th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

THURSDAY, AUGUST 16th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Mr. Dunn: Diseases of the Eye. 4 p.m.: Lecture:—Mr. Dunn: Demonstration on Selected Eye Cases.

FRIDAY, AUGUST 17th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Diseases of the Throat, Nose, and Ear. Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 p.m.: Dr. Ball: Some Points in Middle Ear Suppuration (with lantern slides).

SATURDAY, AUGUST 18th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

Vacancies.

Liverpool Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary £120 per annum, with board, washing, and lodging at the Hospital. Applications to the Port Sanitary and Hospitals Committee, Town Clerk, Municipal Offices, Liverpool.

Worcester County and City Asylum.—Third Assistant Medical Officer. Salary £130 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Powick, Worcester.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Fermanagh County Infirmary, Enniskillen.—House Surgeon. Salary £52 per annum. Applications to C. Wilson, Secretary.

County Borough of St. Helens.—Lady Assistant Medical Officer. Salary £160 per annum. Applications to the Chairman of the Health Committee, Town Hall, St. Helens.

Northern Infirmary, Inverness.—House Surgeon. Salary £100 per annum, with board, &c. Applications to Mr. Duncan Shaw, W.S., Inverness.

County Asylum, Dorchester.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Chesterfield and North Derbyshire Hospital and Dispensary.—Senior House Surgeon. Salary £120 per year, with board, apartments and laundress. Applications to the Secretary at the Hospital.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, fuel, lighting, washing, and attendance. Applications to the Medical Superintendent.

Preston Royal Infirmary.—Resident Medical and Surgical Officer. Salary £130 per annum, with board, residence, attendance, and washing. Applications to Mr. Walter Davies, Secretary, 5 Winckley Street, Preston.

York Dispensary.—Resident Medical Officer. Salary £120 a year, with board, lodging, and attendance. Applications to W. Drape, Esq., De Grey House, York.

Appointments.

HUGHES, PERCY, T., M.B., C.M.Edin., D.P.H., Medical Superintendent to the Worcester County Asylum, Barnsley Hall, Bromsgrove.

MACLEAN, ALICE W., M.B., Ch.B.Glasg., House Surgeon at the Chorlton-upon-Medlock Dispensary, Manchester.

PHILLIPS, H. J., M.R.C.S., L.R.C.P.Lond., Assistant Medical Officer to the London Open-air Sanatorium, Pinewood, Wokingham, Berks.

Births.

CALVERLEY.—On Aug. 11th, at 21 Earl's Avenue, Folkestone, the wife of J. E. J. Calverley, C.M.G., M.D., &c., &c., of a son.

FLEMING.—On Aug. 7th, at 10 Chester Street, Edinburgh, the wife of Robert A. Fleming, M.D., F.R.C.P.E., of a son.

GIDEON.—On Aug. 7th, at Bridge House, Canterbury Road, Hatcham, the wife of G. V. M. Gideon, M.R.C.S., L.R.C.P.Lond., L.S.A., of a son.

HOLMES.—On Aug. 6th, at Barton Abbey, Oxfordshire, the wife of A. Hewston Holmes, M.D., of a son.

MOON.—On Aug. 5th, at High Beach, Victoria Parade, Broadstairs, the wife of E. G. Moon, M.R.C.S., L.R.C.P., of a daughter.

SLADEN.—On Aug. 7th, at 2 Talbot Road, Highgate, the wife of Reginald J. Lambart Sladen, M.R.C.S., L.R.C.P., of a son.

Deaths.

KALAPESI.—On July 16th, at Frere Road, Fort, Bombay, of tuberculosis, Dr. R. M. Kalapesi, M.B.Lond., D.T.M.Camb., M.R.C.S., &c., in his 37th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, AUGUST 22, 1906. No. 8.

NOTES AND COMMENTS.

The Townshend Case.

A little sensationalism has been infused into the dead season by the inquisition into the state of Lord Townshend's mind, and most people who take the trouble to read their papers are well fortified in the facts and consider themselves competent to pass a judgment on them. From the medical point of view the case presented many features of interest as regards both the scientific and medico-legal sides. The Marquis was one of those amiable, puny, feeble-minded creatures who are met with frequently in the humble walks of life, and after being kicked at school and buffeted by the world gradually find a niche in a benevolent relative's home and do nobody any harm. Their mental classification is puzzling, for they do not fit exactly into any of the alienists' pigeon-holes, but so long as they have a limited range of action they do not need certification to protect either themselves or society. They may be regarded as sane or insane as circumstances require, sane when harmless and insane when actually harmful. The Marquis was very properly certified as insane when he was found to be wasting his money on a lot of undesirable parasites, and now that he will have a committee responsible to the Lord Chancellor for his property, he may with fair safety be allowed freedom of personal action.

Insanity and the House of Lords.

Mr. Swift MacNeill might be trusted not to allow so favourable an opportunity to pass without having a dig at the hereditary chamber. He has had it in *The Times*, and a justifiable dig it is. He points out that under the Bankruptcy Act, 1883, a peer who is bankrupt is debarred from sitting in the House of Lords, and that in a Bill introduced by Lord Salisbury an attempt was made to restrain members of that House guilty of moral obliquity from taking part in the affairs of the nation. But there is nothing to prevent a peer who is an idiot, an imbecile, or a lunatic from speaking and voting in the upper chamber, and thus we arrive at the extraordinary result that a man who is acknowledged to be incapable of looking after his own affairs is considered by the Legislature a fit person to aid in the revision of the decrees of the people's representatives. The supporters of the hereditary principle in politics will have to take care lest they find the Marquis Townshend taking his seat in the House of Lords and voting on the Education Bill. Such a paradoxical incident would produce the *reductio ad absurdum* which kills more quickly than abuse.

Kissing the Book.

From a correspondence on the subject now going on in *The Times* it is evident that what may be called sanitary reform in the method of administering the oath in the courts of law makes but slow progress, mainly owing to the prejudice or indifference of judges and magistrates. It is stated that the books in some courts are too filthy for description, and that many persons putting their lips to them would never be allowed to use the same article as others in any place where the most common sanitary precautions were taken. In spite of this, many judges and magistrates still show so much reluctance to accept the alternative of swearing by raising the arm that witnesses are often constrained to undergo a loathsome ordeal which they detest and from which they have a right to escape. Judge Emden has shown an example in this matter. Twelve years ago he caused notices to be placed in his courts drawing the attention of the public to the fact that they were entitled to be sworn with uplifted hand in the Scotch fashion, and during all this time nearly every person has elected to take the oath in that way. It is satisfactory to add that Judge Emden's examplehas been now followed at Lambeth Police Court. Within the past few days instructions have been given that witnesses are to be offered the option of being sworn with uplifted hand. So far, it is stated, the great majority of witnesses have availed themselves of this offer. It seems a pity that no high authority exists having the power to insist upon the carrying out of this reform throughout all the courts of every grade within the kingdom.

The Peculiar People.

In our leading articles and in contributions by correspondents after the recent trial for manslaughter in the Christian Science case, the law as to the responsibility of persons in charge of the sick with regard to the summoning of medical assistance was explained with sufficient clearness. It is evidently incumbent upon parents and guardians of children, and upon those who have the charge of patients mentally irresponsible—idiots, imbeciles or lunatics—to call in medical help when needed;

and if a death ensues owing to neglect of this duty a charge of manslaughter may be brought forward. In an inquest on such a case everything turns upon the question—Could life have been saved or prolonged by medical science? Doubt upon this point led to the verdict of "Death from natural causes" in the case investigated at the West Ham Coroner's Court on Thursday last. A child, age six months, had died from diarrhœa. No medical attendance had been procured by the parents—members of the "Peculiar People"—but the usual rites of their sect had been performed. Dr. Angus Kennedy deposed that death was due to epidemic diarrhœa, and that, whilst he thought that medical attention would have relieved the child, he was not prepared to declare that its life could certainly have been saved. He added that a great many children were dying from summer diarrhœa at the present time, whether medical aid was called or not, and that the death-rate of London had increased 4 per cent. during the last three weeks from this cause alone. Dr. Angus Kennedy's evidence no doubt determined the character of the verdict, but the fact that the jury having added that they considered a medical man should have been called in made it obvious how near they had come to pronouncement of a less merciful judgment.

LEADING ARTICLE.

UNIVERSITY EDUCATION IN IRELAND.

THE correspondence which has been provoked by the somewhat premature divulgement of schemes for the reform of University education in Ireland, still rages in the daily papers, and has led to the publication of much interesting information. Briefly, the present position is as follows:—The Junior Fellows of Trinity College, many of the professors, and a considerable body of representative Catholic laity desire a scheme of mixed education in Trinity College, since they appreciate the evil results which must flow from the division of the youth of Ireland into two hostile camps. The Catholic hierarchy refuses to accept such a scheme, but professes itself willing to accept either a second college in Dublin University, a new Catholic University, or a college in the Royal University, any or all of which necessarily meaning the establishment of a sectarian as opposed to a non-sectarian college. Trinity College refuses to agree to the establishment of a second college in the University of Dublin, with which she is indissolubly connected, presumably on the grounds that, as was shown by the Royal Commission on University Education in 1901-3, the thrusting of a sectarian college into an institution which had up to that time been non-sectarian had led to many ills. Letters from members of the Gaelic League show that not alone must the new or reformed college, whichever it is to be, be acceptable to Catholics, but it "must be made thoroughly Gaelic and national in character." And the Corporation of Cashel give vent to the hope in regard to those members of the Catholic laity who have advocated the re-casting of Trinity College that "each of these deserters will be adequately dealt with by all honest Catholics." On the other hand, the *Church of Ireland Gazette* strives to emphasise as a fact that Trinity College is a Protestant institution, and says that it is for the "Church and Churchmen to consider . . . . whether they can sanction . . . . this proposed transmogrification of their Alma Mater." We do not envy the Commissioners the task before them, nor do we covet their laurels which the result of their labours will bring. If the wishes of what may be termed the moderate party, who seek for mixed education, are to be thrown aside in order that Trinity College may be converted into a Protestant institution and a new Catholic institution created; if the cries of the Gaelic League for an institution which will be "national" are to be answered; if the demands of domestic economy and the warnings of past experience are to be neglected, then the laurels of the Commissioners will not be valued by posterity. If, on the other hand, they, as men of business, shut their ears to the charms of the sectarian and the politician and attend to the duty for which they have been summoned, they will receive the unanimous condemnation of all parties of extremists, and the result of their labours will probably be repudiated by the Government which appointed them. We have referred to the demands of domestic economy and the warnings of past experience, and perhaps we should explain our meaning. With regard to the former, it is simply this:—Ireland, with a diminishing population, and an extreme necessity for obtaining the best value for her money, is seeking to incur the expenses of a double, treble or quadruple university establishment, not in order that she may receive greater educational advantages, but that she may indulge in the privileges of having for each man a teacher of his own particular religious and political colour. Carry on such a scheme a little further and Ireland will be a grand country for the educationalist in search of employment. There will be numerous posts and no pupils. With regard to experience, our allusion is to the increasing lunacy for which—if a bull be allowed—no one can find a cause, yet the origin of which everyone knows. Is the establishment of religious and political universities a good panacea for a country already driven to the borders of insanity by religious and political excitement? *Similia similibus curantur?* In conclusion, we desire to quote, with slight alteration, the concluding sentence of a well-reasoned letter which Mr. Edward Gwynne has contributed to the general discussion: The interests of the students in a mixed college will be safe so long as they are in the hands of men who have won their position by their merits, and whose first object will be the welfare of their university, not that of a particular Church. Perhaps we may also add, the interests of the nation will be neglected when the education of its sons is placed in the hands of the politician.

NOTES ON CURRENT TOPICS.

Insurance against Doctors' Bills.

From time to time an enterprising newspaper or an association of some kind brings out some scheme for supplying people with doctors, but, as our readers are well aware, these schemes are nearly always open to grave objection. Either the medical profession is exploited for the benefit of the association, or attempts are made to wean patients away from their own doctors, or some particular doctor is forced on subscribers whether they will or no. So many and ingenious are the ways by which such evil designs are foisted on the public that one begins naturally to distrust everything presented to our notice. Our attention, however, has recently been drawn to a new policy issued by the Central Insurance Company which we have carefully examined, and in so far as it goes it seems to us not only to be free from objection but positively to cut the Gordian knot that so many have hacked at. Under this policy the assured by paying a certain addition to his premium gains the benefit of having his doctor's bill paid when suffering from the accidents and diseases covered by the policy. At the end of the illness his own doctor sends in his bill to the patient, who presents it to the company and receives a cheque. We do not pretend to have examined into the basis in which the requisite calculations are made, but the company are satisfied that they are in a sufficiently strong position to undertake their responsibilities under this head, and we can only add that if a workable scheme can be produced by which medical attendance on all illnesses could be covered by premiums paid during times of health, the medical profession would warmly welcome it. It happens from the nature of circumstances that the doctor's bill is incurred when the patient is least able to meet it, and too often the doctor is either only paid after long delay, or not paid at all. If, therefore, a patient can insure against his liabilities to his doctor, no one would be better satisfied to have such patients than he who has attended many of the improvident and reckless.

The Struggle for Existence.

There was a pathetic advertisement in the *Times* the other day, and we are glad to see that it is already receiving quotation in various journals. It ran :

AN EAST-END (London) MEDICAL MAN, B.A., Cantab., who has never had a day's holiday or a Sunday's rest since he has been in practice, and who has not sufficient capital to purchase a more comfortable living, would like to change his profession. He has taken honours in Science, so judges himself capable of filling a Post as ANALYTICAL CHEMIST. Having good credentials and references, he hopes that manufacturing firms, &c., will give his advertisement their consideration.

Those who are in a position to judge know only too well that the East End (London) medical man is typical of a large class. A man may be well educated at a university, he may be competent in his profession, he may be diligent and industrious, and yet through want of capital and friends he may be reduced to drudgery such as the worker in the factory and the domestic servant have no idea of. If the man who has never had a day's holiday or a Sunday's rest were of the "working classes," he and his friends would be in a state of justifiable rebellion ; but being an educated gentleman he has to grin and bear it. We cordially hope a firm of manufacturing chemists may be able to help our colleague.

Lunacy Procedure.

One cannot be altogether surprised that the papers during the last few days are full of comments on the certification of the insane and on that happy hunting-ground, the profit accruing from private asylums. The lunacy laws in theory provide adequate safeguards against malpraxis and mistaken certification by compelling the signatures of two independent medical men to a certificate, by providing for the co-operation of a magistrate, and by the notification to the Commissioners in Lunacy of all fresh certifications. Moreover we believe strongly that the power placed in the hands of medical men is used in as honourable fashion as it would be impossible to obtain in any walk or rank of life. The evidence that people are maliciously certified as insane, at least for the last fifty years, is conspicuously lacking, and critics are always discreetly silent on the subject of actual conspiracy. In one point, however, they are right, and that is in insisting on the insecurity of patients who may have been mistakenly certified and who are dependent on the visit of the commissioners to establish their sanity. Far from being the fault of the commissioners themselves, this unfortunate possibility is due to the utter inadequacy of the staff at headquarters. There is no harder-worked body of public servants than the commissioners, who have an amount of administrative and inspecting work to do that it is quite beyond their powers. If the public require, as they have the right to require, proper inspection of all lunatics and asylums, they should insist on having the present staff multiplied by ten. If they are not prepared to find the necessary funds, then like Eliza Hawkins, they have only themselves to blame.

Midwives Act Failure.

The Midwives Act, conceived in ignorance and born in fatuity, can, as has frequently been pointed out, only be of benefit to the public if administered under medical supervision and in consonance with medical opinion. At present chaos reigns throughout the land from the egregious Central Midwives Board to the humblest Betsy Prig who uses her obstetric scissors alternately to cut the umbilical cord and trim her luxuriant nails. In most districts it is a farce, and a farce not untinged at times with tragedy. It is perfectly hopeless to expect the class of women who become midwives to maintain a high standard of work unless they are under direct supervision and not merely "inspected" once or twice a year. An

example of how badly the bad machinery provided by the Act may break down is provided by the county of Hampshire, where last week Colonel Grimston, Chairman of the General Purposes Committee, presented a report to the County Council saying that since the Council had delegated their duties to the urban and rural district councils, the work over a third of the county had simply not been undertaken. The Council, after a long discussion, agreed to form a central committee, on to which they could co-opt ladies to work the Act, and then by way of letting the committee work out its own salvation, the Council accepted an offer from the Hampshire Nursing Association to inspect midwives at a guinea a head! What qualifications have the Hampshire Nursing Association for the work, we wonder, and why should the County Council pay such a price for their assistance?

Lourdes.

ONE result of the religious struggle which is raging in France at the moment is that Lourdes is more than usually full of victims of disease and superstition. The rumour has gone forth that the French Government are likely soon to close Lourdes as a health resort, but whether it be true or not we have no definite information. Certainly from all accounts the Government might well turn their attention to the state of things prevailing in the town. In the hope of cure the halt, maim, and blind in all stages of sickness are being bundled into the town by their relatives, while railways, hotel proprietors, and all the hangers on of the resort are making what they can out of the poor folk. We suspect it is little enough in most cases, as the patients are drawn from the peasant class who have not much in the way of savings to spend, but generally it is their all that goes in the pilgrimage. The accommodation provided by the town is scanty and the people are herded, sick and well, into shells under sanitary conditions described as revolting, and the whole performance seems to be an outrage on decency. In this country we have our troubles, but we are, at any rate, spared having a Lourdes.

The Sunday Fund.

CHARTERS, like wives, are good things to obtain, but, like wives, they are correspondingly difficult to be dispossessed of. Charters are fashionable just now, and all sorts of bodies are applying for them. Even the herbalists want one. But chartered bodies, whether companies or colleges, once created, are apt to operate against the public interest, however worthy and benevolent their original function. The Metropolitan Hospital Sunday Fund, than which no body could have a more noble aim, are applying for a charter, but we cannot help thinking their demand is premature, and we earnestly trust that they may see their way to hold over their application for the present. The subject of charitable hospital maintenance is now in the melting-pot, and till it can be moulded into consistent form it is in the highest degree unwise that any particular or sectional interests, especially vested interests, should be created. Hospital abuse has never reached the pitch that it has attained of late years, and the extravagance of certain hospitals which can rely on having their debts paid is notorious. Till some body can undertake the central control of the London Hospitals, no particular body should seek to acquire particular powers. If the Hospital Sunday, the Saturday, and the King Edward VII. Funds combined their energies—there is no reason in logic for their separate existence—a board might be formed which would command general respect. At present there are too many people pulling different ways, and the public and the medical profession suffer.

Medicine Tasting.

THE "therapeutic nihilist" is regarded by those physicians who believe in treatment as the outcome of a want of knowledge of the actions of drugs and the methods of combining them artistically. There is a great deal to be said for such a view, for certain it is that in the present day when bacteriology and other cognate subjects loom so largely in the medical curriculum, therapeutics and pharmacy have to take a back seat. Consequently the newer order of practitioner is but ill-equipped with the necessary armament to please his patient, even if he be all the better equipped, as one must hope he is, for cure. Some such experience, we take it, must have induced the medical profession at Los Angelos to appoint a lady as a "medicine-taster," a post which a certain Miss Mary Brooks holds with satisfaction to herself and advantage to the patients. So far—we have no information as to how long she has held her delectable appointment—Miss Brooks looks well and happy, and is said to enjoy the best of health. We should imagine that the amount and variety of medicine she must consume would suffice to nip any incipient ailment in the bud, and so it seems to do. Miss Brooks is said also to enjoy a large salary, so that it is unlikely that she could be induced to come over here; but there must be many patients who would gladly employ such an expert, and we commend this new avenue of industry to "superfluous women" on the look out for a "job."

Ventilation in the House of Commons.

HIS MAJESTY'S faithful Commons are constantly quarrelling with the air they breathe during the performance of their "duties," and when it is considered that some 670 of them, more or less according to circumstances, a mass of pressmen, a couple of galleries full of eager constituents, and an indefinite number of distinguished strangers sit for some nine hours continuously in a chamber of limited size, whose windows will not open, the wonder is that any live to grumble. The ventilating machinery of the House was ingeniously designed by Dr. Boswell Reid and Mr. Barry some fifty years ago, and take it all round

it is as good a system as obtains in most public meeting places. Still it is far from being perfect and the just-published report of the last committee appointed to examine the question does not materially help from the practical point of view. The proportion of carbonic acid, the temperature, the relative humidity and the bacteriological purity of the air are found to be all that can reasonably be expected, and the committee feel they must still continue their researches if they are to locate the faults in the arrangements. It is significant to notice that what members most complain of is the languor and lassitude produced by sitting in the chamber, and if we are not presuming to step in where angels fear to tread, we should venture to suggest that what is needed is fresh air. Every day experience informs us that outside air has an indefinable quality of "freshness" which indoor air lacks, and this quality cannot be analysed in beakers or cultivated in test tubes. Opening the windows of the House might make the members "sit up," but it would cure their lassitude and stimulate their loquacity. There are those who might think that the latter event was an equivocal blessing.

Law for Lawyers and Law for Doctors.

At the Lambeth Police Court on Friday last, the fact was once more forcibly illustrated that it is virtually impossible for an unqualified man to practise under false pretences as a solicitor. He cannot with impunity assume a title implying in the remotest way that he is legally qualified, he cannot employ terms or expressions in his business letters capable of being so misinterpreted by a simple reader. The law is clear, the Law Society very much on the alert, and magistrates invariably ready to inflict severe penalties on offenders. On the same day at the County of London Sessions the grotesque comparative weakness of the Medical Acts was once more exposed. A quack was sentenced to fifteen months' hard labour for assaulting a girl who had been for many years an epileptic and whom he had undertaken to cure. The quack had no medical qualification whatever, but had for a long time succeeded by his plausible manner in imposing upon ignorant people and passing himself off as a doctor. The latter offence, unless the pretender is stupid enough to adopt a title specifically named in the Medical Act, does not render him amenable to the law, and whatever offence in this direction he may be guilty of, it is not by any means certain he will be interfered with, since there exists no public prosecutor with the obligation of enforcing the law. The Medical Council has no power to interfere, and there exists no public or professional organisation similar to the Law Society discharging like functions in the control of the profession and safeguarding its own interests as well as those of the public. Hundreds of medical quacks are in practice all over the country; a large proportion of them are really criminals living by the plunder of suffering humanity, and carrying on their nefarious trade with perfect safety so long as they do not incur a charge of manslaughter or commit some offence which brings them within the scope of ordinary criminal statutes. It is difficult to believe that this state of things could be allowed to continue if the people and the Legislature which represents them were once made fully to realise the evils and abuses which the present system allows.

PERSONAL.

Mr. Herbert H. Brown, M.D., has been appointed a Governor of the Ipswich School, in accordance with the requirements of the new scheme, dated May 30th, 1906.

The Royal Dental Hospital of London has received £500 from the executors of the late Mrs. Hannah Finnie, with the stipulation that the amount be invested, and the income therefrom applied to the objects of the hospital.

Mr. H. T. Butlin, D.C.L., F.R.C.S., has been elected vice-chairman of the Committee of Medical members of the London University Senate.

The Moxon Medal of the Royal College of Physicians, which is given every third year, has been awarded to Dr. Jonathan Hutchinson, F.R.S.

Professor von Bergmann has been summoned to Constantinople. One of the Sultan's doctors has been promoted to the rank of General.

Baron Eiselberg, Professor of Surgery at the Vienna University, has recently been operated on for appendicitis. The morning before the operation, Baron Eiselberg himself performed two serious operations on patients, which lasted in all four hours.

It is reported that Dr. Frank Billings, who went from Chicago to New York to attend the late Mr. Marshall Field, the millionaire, is to receive a £5,000 fee. This is said to be the largest fee received by an American physician.

Dr. Seymour Stritch has been appointed a Justice of the Peace for the City of Dublin.

Dr. M. J. Russell has been appointed Superintendent Medical Officer of Health for the South Dublin Union.

Mr. F. H. M. Parker, M.A.Oxon., barrister-at-law, has been appointed Secretary to University College Hospital Medical School.

The Chief Secretary for Ireland has appointed Sir William Thomson, C.B., M.D., to be Inspector of the Schools of Anatomy for the provinces of Leinster, Ulster, and Connaught, in the room of William J. Martin, Esq., M.D., deceased.

At a recent meeting of the Court of Assistants of the Society of Apothecaries of London, held at the Society's hall, Blackfriars, Mr. E. Parker Young, M.R.C.S., L.S.A., was chosen as Master, and Mr. George Wilks, M.B., M.R.C.S., L.S.A., and Mr. F. Gordon Brown, M.R.C.S., L.S.A., surgeon to the City of London police, were elected respectively as Senior and Junior Wardens for the ensuing year.

The court of the same Society unanimously resolved that the freedom of the Society should be conferred upon Alderman T. B. Crosby.

A CLINICAL LECTURE
ON
TUBERCULOSIS AND DISEASES OF THE SKIN.

By JONATHAN HUTCHINSON, LL.D.Oxon., Hon.M.D.Dub., F.R.C.S., F.R.S.,
Consulting Surgeon to the London Hospital, the Hospital for Diseases of the Skin and Royal London Ophthalmic Hospital.

GENTLEMEN,—In continuation of our lectures, I have to-day to deal with tuberculosis in reference to its manifestations on the surface of the body, that is, diseases of the skin which are in some way connected with the presence of the tubercle bacillus. Physicians have been disposed to claim tuberculosis as their own peculiar possession, and some have appeared to regard diseases of the skin with a feeling approaching almost to contempt. I hope to convince you that tuberculous diseases of the skin are well worth studying separately as to their own peculiar characteristics, and also as to their bearing upon other forms of tuberculosis.

There are a number of different affections of the integument, not, I think, all of them the results of inoculation, although one of the questions that one constantly has to investigate in reference to tuberculous manifestations on the surface of the body is, Are these all the result of inoculation? I suppose most of you are aware that the common conceptions regarding tuberculosis are in favour of most forms of tuberculosis being the result of the introduction of the tubercle bacillus into the body. I refuse to accept the view that pulmonary phthisis, for example, usually originates from actual infection, or, in other words, that "the patient took in the bacillus, and then he got pulmonary disease." I think that is to a large extent a mistake, as I shall endeavour to show in relation to various skin diseases. I shall endeavour to impress upon you the fact that the tubercle bacillus is quite capable of remaining latent for a long time, and yet is quite ready to be active when a favourable time comes. That is an important general doctrine as regards all forms of tuberculosis. All varieties of tuberculosis depend more or less remotely on the presence of the tubercle bacillus, but this organism is often not very active, and sometimes has no tendency to produce symptoms at all.

Perhaps the best-known variety of tuberculous affections of the skin is that which goes by the name of lupus vulgaris. It is generally acknowledged that lupus vulgaris is a tuberculous disease of the skin. The tubercle bacillus has been found in the granulomatous lesions which characterise the disease. Here is an example (diagram shown) of the ravages of lupus vulgaris on the surface of the nose. It has for years crept serpiginously from its edges until it has eaten away the alæ and the soft part of the skin of the nose. Lupus vulgaris is not a disease of the bone; it begins in the skin and keeps to the skin. This (diagram shown) represents a patch of lupus vulgaris on the buttock, spreading at its edge. Here is an example (diagram shown) of lupus scrofulosorum. Its circular outline is suggestive of syphilis. In my last lecture I referred to the impossibility of diagnosing between tuberculous lupus and syphilitic lupus merely from the external appearance of the part affected. Tuberculous lupus may have syphilis as a partner in the concern, so to speak, and in like manner syphilitic lupus may have tubercle associated with it. Only the skilled pathologist can determine whether lupus is purely syphilitic or purely tuberculous, or whether it is a result of the union of the spirochæte and the bacillus. Here is another example (diagram shown) illustrating, as in the first case, the destruction of the alæ nasi and spreading over the patient's face. Here is another (diagram shown) beginning with the nose and spreading to the two cheeks equally. These three cases illustrate the great probability of the disease beginning from the nose. The nose is the part which is most subject to lupus, the reason being that the nose is easily chilled. The chilling deranges the nutrition of the part and thus causes lupus. There is very little of this disease in the tropics. The cold of the English climate is remarkably efficient in producing lupus on the face. Here is another example (diagram shown) of lupus on the face and here another (diagram shown) with large patches on the buttocks and hand, and a patch on the back of the calf of the leg. In extremely exceptional cases patches of lupus vulgaris may appear on the scalp, as has happened in these three examples (diagrams shown). Here is an example in a child (diagram shown) of lupus vulgaris which is eating away the soft part of the nose. In this example (diagram shown) the disease affects the lips, in this (diagram shown) it has begun in the nose, in this (diagram shown) it has commenced in the nose and spread to the cheek, in this (diagram shown) the disease has taken away the soft part of the nose and spread to the cheeks; in this (diagram shown) it has begun in the centre of the nose and no one could tell by its appearance whether it was a case of syphilis or not; it looks like syphilis, but the history would decide the point. Here is a case of multiple lupus (diagram shown) occurring in three or four places, but not in the nose at all. Probably some little injury has produced it. Here is another diagram (shown) illustrating a case of my own, in which during a period of twenty-five years the disease slowly spread to the cheek. Here is another example (diagram shown) illustrating destruction of the nose and the spreading of the disease equally and symmetrically on the cheeks and neck, and tending to become crusty. This example (diagram shown) shows the disease to have spread from the nose to the cheeks and down to the neck, and producing little satellites near to it by infection. The tubercle bacillus or its products have destroyed certain parts and then gradually spread into healthy and unaffected tissue at their borders. The treatment consists in exterminating the bacillus by destroying the entire area which is diseased.

(a) Lecture delivered at the London Hospital, June 26th, 1906.

I want to illustrate another fact in reference to this disease of lupus vulgaris, and that is, it may be multiple. There is a stage in which the disease is not only infective by contagion and continuity, that is, gradually spreading from the first part infected, but there is a stage in which the lupus may be scattered all over the surface of the body.

It is an interesting fact, with regard to multiple lupus, that when the lupus is going to spread all over the skin, it does so within a few weeks of the beginning of the attack. I think that in this particular form of lupus there is some element of contagion, not due to the tubercle bacillus alone, but to a partnership between it and some other virus which makes the disease contagious wherever the patient scratches himself. During a period of from three to six months from the beginning of an attack of lupus, the patient may, by scratching himself, produce patches all over his skin. But, after six months has passed he may scratch himself as much as he likes and he does not get multiple patches. It is clear, therefore, that in the very early stages of the implantation of the tubercle bacillus in the patient's skin there is something which makes external contagion possible. Lupus vulgaris is not a disease due to the diffuse presence of the tubercle bacillus in the blood. My reason for making this assertion is the fact that the manifestations of the disease are never bilateral or symmetrical. Anything circulating in the blood is likely to bring out its manifestations in what we call a bilateral or symmetrical form. I have mentioned to you the main facts as regards lupus vulgaris, which is the best acknowledged example of tubercular lupus.

Concerning other forms of lupus there is a certain amount of dispute. There are various other modifications of the disease. You may, for instance, get cases of what are termed acne lupus. I call it *acne* lupus because I think the expression conveys more to anyone hearing it than if I called it *acniform*. By acne lupus I mean that particular variety of lupus in which the patient has real acne on the face. Previously he has had inflammation of the sebaceous follicles of the face, but, being a tubercular subject, this inflammation has assumed a condition of lupus, a condition in which the disease has a tendency to spread at its edge. This tendency to spread is proof that there is something infective, and that something is in connection with the tubercle bacillus.

Another form of lupus is that known as lupus eczematosus, which manifests a tendency to heal and then break out again, and which you cannot cure like pure eczema.

You may also get cases which are known as lupus erythematosus, a disease which begins generally on the face, but is very rarely confined to the face, spreading also on the hands and arms. There is a great dispute as to whether this disease is really lupus. I think it certainly deserves the name of lupus, because it destroys the skin and leaves a scar where it has been. The tubercle bacillus is never found in lupus erythematosus, but, nevertheless, I have not the least doubt that it is really a tubercular disease. That view is strongly supported by clinical evidence, which, I maintain, ought not to be wholly thrust aside by evidence obtained from observation by the microscope. This disease of lupus erythematosus is constantly seen in patients suffering from pulmonary phthisis, and I claim that it is tubercular in character. There are certain cases of lupus erythematosus which it is exceedingly difficult to distinguish from lupus vulgaris, and sometimes you get these two forms of lupus in the same patient. But, as I have already said, I have no hesitation in classing lupus erythematosus along with lupus vulgaris as a tubercular disease.

The next skin disease to which I would draw your attention is that termed lichen scrofulosorum, a form of lichen which occurs in scrofulous patients. None of us have any idea of scrofula except in connection with tuberculosis. It is very often in association with other morbid diseases, but still it is always connected in some way with the tubercle bacillus. The term *lichen scrofulosorum* means lichen occurring in a patient who has the tubercle bacillus or some of its products. This lichen scrofulosorum is a very interesting malady which we are only just beginning to recognise in England. It manifests itself at first as a little brown spot on the skin, with other tiny brown spots near to it. This is a typical example (diagram shown) of lichen scrofulosorum in the final stage of the disease. Lichen scrofulosorum is sometimes called, on the Continent, miliary tuberculosis. The tubercle bacillus has been found in lichen scrofulosorum, and I do not think there can be the slightest doubt that it is purely a tubercular disease. I remember a man who came to me suffering from lichen scrofulosorum. His father had died of pulmonary disease and his brother also came to me with tubercular gland disease. I connect that lichen scrofulosorum in that man with tuberculosis in his father and scrofulous gland in his brother. Lichen scrofulosorum, in the first stage, does get well. I have seen that man quite recently and his skin is perfectly cured. You will, I think, be willing to regard that case as proof that this disease of lichen scrofulosorum, in its initial stage, is perfectly curable.

I now come to a very interesting malady which has received the name of Darier's Dermatosis. In this affection the skin of the trunk and especially the chest and abdomen is covered with small comedonous papules. They are arranged somewhat in groups, but may become confluent and almost universal. The condition lasts for years and may become more and more aggravated the longer it lasts. Its subjects are usually young adults, but it is a rare affection and no large number of typical examples have been placed on record. The distinguished physician whose name it bears discovered certain ovoid bodies in the deeper layer of the corium which he thought were zoospores and of a parasitic nature; but I believe it is now generally acknowledged that the appearances are the result of degenerative changes and not of a parasitic nature.

We have recently had under observation at the Polyclinic two excellent examples of this skin disease, both of them kindly brought to us by Dr. Hartigan from the Blackfriars Hospital. The investigations of these two cases has convinced me that the malady is only an exaggerated form of Lichen scrofulosorum. I have arrived at this conclusion by observing the differing characters of the eruption in different parts of the surface, and by comparing its features with those figured by

authors under the latter name. I show you drawings and photographs of Dr. Hartigan's patients, and I show also drawings from various atlases illustrating the form of lichen to which I refer. These are certainly all gradations in the changes delineated, and I do not think that anyone examining them can doubt that they should all receive the same name.

Darier figured in one of his cases an acutely inflammatory condition of the skin of the pubes and lower part of abdomen, resembling an acute, exudative eczema. Now one of our recent cases had this same complication, though not the abdomen but the forehead and scalp were its sites. The clinical history of the cases usually fits in with the diagnosis of scrofula. It may be added, in further corroboration of the diagnosis, that Dr. Hartigan found the ovoid bodies described by Darier in great abundance in one of his patients, and the two were exactly alike.

I feel justified, then, until some evidence to the contrary is forthcoming, in asking you to regard Darier's Dermatosis as a very chronic and aggraved form of lichen scrofulosorum. Thus we effect a simplification, and restrict our nomenclature.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week's issue will be by Herbert Stanley French, M.D.Oxon., M.R.C.P., Medical Registrar, Guy's Hospital, on "Some Points with Regard to Empyemata," delivered at Guy's Hospital, June 6th, 1906.*

ORIGINAL PAPERS.

HÆMATEMESIS.

BY GEORGE CHAPPEL, M.D. CANTAB.,

Physician to Out-Patients, Tottenham Hospital.

IN diagnosing and treating a case of hæmatemesis our first and often great difficulty is to make out definitely the source of the bleeding. In addition to gastric ulcer (whether simple or malignant) there are many causes which may give rise to the presence of blood in the stomach, and to its being subsequently vomited. The commonest and most important of these is hæmoptysis. The history will often give us a clue, but is not infallible, as patients who have lost a great deal of blood are often too nervous to give a history which can be altogether relied upon. The point to be noted especially is the condition of the blood. In hæmoptysis the blood is of a bright scarlet colour, alkaline in reaction, frothy from admixture of air, and comes up with a cough; usually there has been a cough before the onset of the hæmoptysis. In hæmatemesis the blood is usually more or less altered in colour, being darker from the action of the gastric juice; on standing it tends to become brighter from taking up oxygen from the air. It will probably be acid in reaction, and may be mixed with particles of food. With hæmatemesis there is often associated a slight cough due to irritation set up by the passage of the vomited blood over the orifice of the larynx. In addition, however, in true hæmoptysis there may be some hæmatemesis from blood from the lungs having been swallowed. Roughly, we may say then that if the blood is preceded by cough the hæmorrhage is from the lungs, if the cough is coincident with the blood the probability is that it comes from the stomach.

In epistaxis, or in fracture of the base of the skull, if the patient is unconscious, blood may run down the œsophagus and be swallowed so that it enters the stomach and when rejected is hæmatemesis. Oozing from the tonsils, gums, carious teeth, or pharynx in various diseases may again simulate slight hæmatemesis. Anæmic girls not infrequently speak of having brought up blood which is small in amount and occurs in the early morning. In these cases blood probably comes from the naso-pharynx. Feigned or hysterical hæmatemesis is due to continual gum-sucking, self-inflicted wounds or extraneous blood introduced into the mouth.

In the œsophagus we occasionally get varicose veins which ulcerate, and the blood runs down into the stomach; this when vomited is indistinguishable from true hæmatemesis. Carcinoma of the œsophagus and an aortic aneurysm leaking through the œsophageal wall will also cause the same condition.

In *True Hæmatemesis* the blood is usually forcibly vomited and may be expelled through the nose as well as the mouth. Before its onset the patient may feel distended, uncomfortable, faint, and become blanched. The blood is generally more or less altered in colour, being darker from the action of the gastric juice; on standing it tends to pick up oxygen from the air and become brighter; it will probably be acid in reaction, and may be mixed with food.

When in copious hæmatemesis the blood is of an arterial character, rapid hæmorrhage from an artery eroded by a gastric ulcer has probably taken place. When, however, it is black, clotted and copious, the hæmorrhage probably depends on cirrhosis of the liver. Small coffee ground vomit is especially associated with carcinoma of the stomach, for the blood is slowly poured out, and is extensively acted upon by the gastric juice.

Frequency.—Repeated large hæmorrhages may be due to ulcerated varicose veins at the lower end of the œsophagus in cirrhosis, or to minute erosions of the gastric mucous membrane, or to gastric ulcer, and may so exhaust the patient as to be fatal. A single hæmatemesis is rarely fatal unless it is due to the rupture of a large aneurysm into the stomach or œsophagus. Small coffee ground vomiting, especially when repeated, is strongly indicative of carcinoma of the stomach; in these cases the vomiting is not due to the presence of blood in the stomach, but is reflex and depends on the irritation of the growth; any blood that is in the stomach being brought up with the gastric contents. In large hæmatemesis the vomiting is the result of the mechanical stimulation of the gastric muscular walls by the distension of the organ with blood.

Causes and Source.—We have seen that the blood may come from the œsophagus as the result of eroded varicose veins; in addition duodenal ulcers may give rise to regurgitation of blood into the stomach and cause hæmatemesis, and an abdominal aneurysm rupturing into the duodenum has been known to cause a fatal attack of hæmatemesis.

In the stomach gastric ulcer is the most common cause; it occurs most frequently in young anæmic women, and is commonly situated near the pylorus. It also occurs in men, but as a rule at a rather later time in life, and may be situated in any part of the stomach. Repeated and large hæmorrhages may occur from very minute abrasions of the gastric mucous membrane. Small ulcers may supervene in chronic congestion of the stomach as the result of localised hæmorrhages into the mucous coat; they may open up a vessel and give rise to profuse bleeding. Dr. Fenwick says that in the passive congestion due to cirrhosis these ulcers usually open up a vein, whereas in that due to cardiac disease an artery is usually eroded.

Among other rare causes of hæmatemesis are aneurysms of the gastric, hepatic, or splenic arteries opening into the stomach. Carcinoma of the stomach may arise at any part of the organ; the hæmorrhage as a rule is slight in amount, and, as we have noted, is usually retained in the stomach, with the result that we get the coffee ground vomit due to the prolonged action of the gastric juice on the blood.

Minute lesions of the gastric mucous membrane occur in acute gastritis as the result of large quantities of spirit, acids, or other poisons. The backward pressure consequent on heart disease, cirrhosis of the liver and thrombosis of the portal vein is apt to set up degenerative changes in the mucous membrane of the stomach and consequently we get a general oozing of blood; this oozing is probably more dependent on the degenerated condition of the mucous membrane than it is on the purely mechanical engorgement.

Further, we get blood extravasated into the stomach in toxic conditions; chief amongst these are septicæmia, yellow fever, acute jaundice, acute yellow atrophy of the liver and malignant forms of the specific fevers. It may occur in typhoid, but is very rare indeed—in fact, almost as rare as the occurrence of typhoid ulcers is in the stomach. In certain blood conditions, such as leukæmia, pernicious anæmia, purpura hæmorrhagica, and hæmophilia, we find hæmatemesis as a symptom.

The question of vicarious menstruation being a cause of hæmatemesis has been long debated. The late Dr. Matthews Duncan said he had been on the look out for it all his life, but had never seen it. About two years ago there was a young woman in this hospital who gave a history of hæmatemesis at each period; she was carefully watched, and when the period came on it was proved that the blood from the mouth was self-induced. I am inclined to believe that most, if not all, of these cases come under this category.

Diagnosis.—If the patient is a young anæmic woman, and the hæmorrhage is large in quantity, the chances are largely in favour of a gastric ulcer; in these cases there is usually a history of pain coming on directly after food, and relieved by vomiting; also deep pressure will probably elicit a point of maximum tenderness. With small erosions of the mucous membrane, however, tenderness may be absent in spite of the fact that the hæmatemesis may be severe and frequently repeated. Examination of the vomit in the absence of hæmatemesis will show an excess of hydrochloric acid. Melæna invariably follows the hæmatemesis.

Gastric ulcer in men is met with at a later period in life; it is associated with more severe pain, and gives rise to anæmia. It is often difficult to distinguish from carcinoma and cirrhosis, but the quantity and quality of the blood will help in the former case, and the absence of enlargement of the liver in the latter.

Sudden hæmatemesis in a middle-aged person without any previous history of illness will lead one to think of cirrhosis, and the diagnosis will be greatly helped if there is an alcoholic history obtained or if the liver and spleen are found to be enlarged and tender. Hæmatemesis in cirrhosis may be preceded by chronic dyspepsia, but the symptoms are not so severe as in ulcer or carcinoma, and tenderness on palpation over the stomach is more general and less acute than in ulcer.

In carcinoma the quantity and colour of the blood is the distinguishing feature, also the fact that there is usually very little melæna to be noticed. In the vomit there is generally an absence of free hydrochloric acid. To this must be added the presence of a tumour in the stomach, and the age of the patient, which is usually, but not invariably, greater than would be the case in a patient with a simple ulcer.

In duodenal ulcer the pain and dyspepsia should supervene about two hours after food, when the process of digestion in the stomach has gone on and the pylorus allows the contents of the stomach to pass into the duodenum; moreover, the tenderness is more to the right of the median line. Melæna often precedes the hæmatemesis.

Hæmatemesis with fever suggests some severe infection like septicæmia, whilst hæmorrhage in other parts of the body points significantly to a blood condition like purpura.

Prognosis.—Hæmatemesis is rarely immediately fatal. If a large artery like the splenic has been eroded by an ulcer, or a large œsophageal varix has ulcerated, or an abdominal aneurysm has ruptured into the stomach, the immediate outlook is very grave, but in cases of ordinary hæmatemesis recovery for the time being at any rate is the rule. When large hæmorrhages occur at frequent intervals death may result from exhaustion, and in such cases the only treatment is to open the stomach and try to secure the bleeding point.

With regard to the more remote prognosis, that is dependent on the pathological condition which is causing the hæmatemesis; the small coffee ground vomit of malignant disease is thus much more grave than the large hæmorrhage of gastric ulcer.

Treatment should consist of rest, and by rest I mean rest of the body, rest of the stomach, and rest of the mind. The patient must be kept absolutely quiet in bed, with the head low, so as to prevent syncope. Mental anxiety must be relieved. Just as in hæmoptysis, patients get very nervous and excited when they are losing a great deal of blood and this nervous excitement is very dele terious. To combat this the best treatment is a hypodermic injection of morphia. The stomach must be kept quiet, and this end is attained by allowing nothing to be given by the mouth; all nourishment must be given by the rectum for a period of time, which varies according to the pathological condition which has caused the hæmorrhage. Thus it may be combated by small pieces of ice being given to such, but I believe the better plan is by giving water by the bowel.

Various drugs have been given as styptics, such as acetate of lead, gallic acid, and dilute sulphuric acid, oil of turpentine ℥xx. every four hours and opium in different forms. The treatment I have found answer best has been Liq. morph. ℥v. combinedwith acid hydrocyanic ℥ii in a teaspoonful of water every two hours while there is vomiting or pain. Adrenalin chloride has been suggested as a local styptic, but I have not had much experience of it. Some authorities consider that calcium chloride in half drachm doses is useful; it is given with a view to increasing the coagulability of the blood.

Feeding must be by the rectum only. The plan I have found answer best is to give large injections of 15-20 ounces of peptonised milk twice a day. A long rectal tube is passed and the peptonised milk allowed to run slowly into the sigmoid flexure the patient lying on her left side. A convenient way is to have an ordinary douche can hung up on the wall, and the stopcock so arranged that the milk runs very slowly. The time occupied by the proceeding is from 20 to 30 minutes. By this means the whole of the milk is retained and none of it returned, as would be the case if it were given rapidly. Needless to say, the rectum must be washed out with an ordinary soap and water enema each day.

One of the reasons why gastric ulcers relapse is, I believe, because food is given by the mouth too soon. In an ordinary case of hæmatemesis from gastric ulcer, feeding should be entirely by the rectum for at least two weeks; then peptonised milk or mutton broth can be commenced in teaspoonful doses and gradually increased if no trouble is caused.

In cirrhosis liquid food may be given much earlier—as soon as three days after the hæmatemesis, provided there is no recurrence. In the small hæmorrhages of malignant disease, food should be given still earlier.

ABSTRACT OF LECTURE ON THE DIAGNOSTIC AND PROGNOSTIC VALUE OF THE TEMPERATURE IN APPENDICITIS,

By L. CHEINISSE, M.D.,

Ex-Interne of the Montpellier Hospitals.

THE teaching of yore with regard to appendicitis was to operate as soon as a diagnosis was made, and although this dogma is still very prevalent in America, there is a tendency in Europe to treat each case on its merits.

The operative method of dealing with this affection is still, of course, the only curative treatment, but the point to decide is the precise moment at which this should be done, hasty operation being by no means exempt from drawbacks. The points that should guide us in advising operation are: The existence of leucocytosis, although this cannot always be considered *per se* pathognomonic, but only suggestive, of abscess formation; another symptom on which stress is laid is the temperature chart. Many authorities assert that appendicitis may occur without causing any noticeable rise of temperature, but is this really the case?

Mr. Rotter, of St. Hedwig's Hospital, at Berlin, from close observation of 100 cases of appendicitis, observed a temperature in eighty-one, nineteen only being apyretic. Of these latter, five were admitted after the tenth day of illness, and may, therefore, have gone through their pyretic period, while the three remaining ones had generalised suppurative peritonitis, so that Mr. Rotter reduces the proportion of apyretic cases of appendicitis to 11 per cent.

Mr. Herzog, from observation of 189 cases, found 139 with fever and 50 without—that is to say, 74 per cent. belonging to the first class and 26 per cent. to the second. The percentage of apyretic appendicitis in these observations is certainly higher than Mr. Rotter's, but it is due to the fact that patients entering hospital sometimes long after the onset of the disease were not eliminated.

Mr. Rostovtzer, out of 152 cases, found a proportion of 9·5 per cent. apyretic.

It is evident from these researches that fever is almost the rule; at all events, that is the case at the onset of the disease. Hyperthermia, too, is a transient symptom, for out of sixty cases treated and cured in the medical wards, Mr. Rostovtzer noted in thirteen cases (45 per cent.) a temperature lasting one day, eleven times (31 per cent.) two days, and in ten cases (15·5 per cent.) three days, while in eleven patients (8·5 per cent.) it remained up for a week, these results thus resembling those obtained by Mr. Herzog. As regards the height of the temperature, most authorities are agreed that it is never excessive.

Mr. Kümmell's statistics show 185 cases in which the temperature never exceeded 100·2° F., 124 in which it oscillated between 100·2° F. and 103° F., and only 61 in which it was higher than 103° F. Mr. Herzog, from observations on 139 cases in the Bethanien Central-Diakonissenhaus, found:—

Temp. 100·2	— 102·2	in 69 cases	= 49·6 per cent.
,, 102·3	— 103	in 40 cases	= 28·8 per cent.
,, 103·2	— 104	in 14 cases	= 10·1 per cent.
,, 104	— 105·8	in 16 cases	= 11·5 per cent.

From these statistics we may draw three important conclusions with regard to temperature—that it is rarely absent in appendicitis, but is of short duration and not of great severity, frequently never rising beyond 102·2-103. What diagnostic or prognostic significance, then, is conveyed by the presence or absence of temperature? Are we right in concluding that, if apyretic, the case is benign? Mr. Rotter has shown that a sudden severe onset does not preclude a prompt recovery, nor does initial apyrexia always indicate a favourable issue.

Although the mere presence of fever is not sufficient *per se* to give valuable information with regard to the evolution of the inflammation, much light is thrown on the case by considering the intensity, the duration and the general course of the temperature.

A certain number of typical temperature curves may be said to exist. In some the temperature rises suddenly, with or without rigor, is maintained for three days at from 100·5 to 103, and is accompanied by a rapid, strong, regular pulse, then with the improvement of the general symptoms and the disappearance of the pain, the temperature drops. The temperature is generally normal five or six days from the onset, the inflammation being strictly limited and of moderate intensity.

In a second group of cases the temperature

keeps up for a long time, rarely exceeding 102°, and the general condition is good, the abdomen is supple and painless, except in the region of the ileo-cæcal valve. Here, again, the peritonitis is localised, and Mr. Rotter recommends in these cases to wait till the ninth or tenth day, and if then the temperature is still above normal, or, if normal, the local signs do not show any amelioration, intervention is indicated, although the general condition may seem satisfactory. If, however, after the third day of the illness the temperature remains high, or even continues to rise, or, after having dropped a little, begins to rise once more to 102·5 or higher, in these cases intervention is called for, not later than the fourth or fifth day, as these elevations of temperature indicate an extension of suppuration, with the risk of general peritonitis and perforation of the appendix. In such cases other signs are present, such as acceleration of the pulse, vomiting, &c.

The same remarks apply to those attacks of appendicitis which to all appearances are benign are subject to recrudescences and to a remittent type of temperature; and it should be our rule that whenever the temperature, having fallen to normal, begins after a short period of apyrexia to rise again, this indicates the presence of pus, and immediate intervention is consequently required.

As to the prognosis in regard to life, the duration of the fever is of less importance than its intensity. Judging from the researches of Mr. Herzog on the subject, out of thirty cases that ended fatally, in fifteen of them death supervened on the third day, the mortality of cases with a temperature under 102·5 treated in the medical wards was 11·5 per cent., whilst those with a temperature of 104 show a death rate of 36·3 per cent.

Useful as hyperthermia is in determining the severity of a localised peritonitis, it is an almost useless factor in considering the prognosis in general peritonitis, for in bad cases of acute septic peritonitis or general peritonitis which is suppurative from the onset, the temperature, after a preliminary rise within the first twenty-four or thirty-six hours, drops suddenly after the second day, often becoming subnormal. The same drop in temperature is seen in cases of general peritonitis following the rupture of an abscess cavity; therefore, in a progressive peritonitis, in which the lesion has a tendency to localisation, the temperature remains high; consequently hyperthermia is of favourable import.

In this group of cases the pulse-rate and the patient's general condition afford far more trustworthy evidence than the temperature; still, it cannot be ignored, for a fall of temperature coinciding with acceleration of the pulse is of very bad augury and denotes the onset of general peritonitis.

One must regard with suspicion all cases in which the rapidity of the pulse is out of proportion to the temperature, an almost certain sign of suppuration. Mr. Jalaguier points out that suppuration in some cases is shown by a progressive rise of temperature from the onset to 104, and others in which, although the local condition remains unaltered, the temperature drops, but the pulse remains rapid.

There remain two points in the temperature to which attention must be directed. These are interesting as much from the point of view of diagnosis as from that of prognosis and the question of intervention. The first is the difference that exists between the rectal and axillary temperature. Usually the difference in pyrexia is from 0·2 to 0·5 C., but Mr. Madelung has pointed out that in purulent peritonitis the difference is even more marked, and may be as much as 1·5. This is confirmed by Mr. Lennander.

The second point of interest is this, and it has been noted by Mr. Rostovtzer that the maximum temperature does not occur between 4 and 6 p.m., as in most pyrexia, but between 9 and 10 p.m.; this statement is based on the result of 686 afternoon observations of 52 patients, 315 times. In 43·5 per cent. of the cases the maximum temperature occurred between 4 and 6 p.m.; in the majority of cases, which formed 44·8 per cent. of the total number, the highest temperature was charted at 9 and 10 p.m.

Mr. Rostovtzer, grouping the cases according to their severity, found that the temperature had a tendency to attain its maximum in the severe cases later in the evening than in cases of less severity. In the mildest attacks (164 afternoon observations on 22 patients), where recovery took place without surgical intervention, 36 per cent. of them showed a maximum temperature between 9 and 10 p.m.; whilst in a second group, in which an operation was performed, 45·6 per cent. of the cases after intervention developed the highest temperature between 9 and 10, whilst before intervention the maximum occurred at this time in 60 per cent. of nine cases of severe appendicitis, with a fatal termination to 56 (65·1 per cent.), gave a maximum temperature between 9 and 10 at night, and 30 (34·9 per cent.) between 4 and 6. In other words, in the very severe cases of appendicitis the maximum temperature occurs between 9 and 10 at night twice as frequently as in the slighter forms. This being the case, it is important to take the temperature frequently in the afternoon, and to be ready to act if the temperature reaches its maximum at a late hour of the evening—*e.g.*, between 9 and 10 p.m.

CLINICAL RECORDS.

A CASE OF SYRINGOMYELIA.

By T. R. BRADSHAW, B.A., M.D., F.R.C.P.,

Physician to the Royal Infirmary, and Lecturer and Examiner in Clinical Medicine in the University of Liverpool.

This case is an instance of one of the rarer forms of disease of the central nervous system, but a disease which presents symptoms so characteristic that its recognition presents little difficulty to anyone who is aware of the possibility of its existence. It is worthy of notice that most of the rarer diseases present striking characteristic symptoms, which make their recognition easy, at least in well-marked cases. Thus, in Addison's disease there is the obvious pigmentation, in myxœdema the no less obvious swelling of the body, in acromegaly the overgrowth of the bones, in myelopathic albumosuria the unique character of the urine. No doubt it is the association with these noticeable syndromes that has led to each of these diseases being recognised as a distinct and definite pathological state; and we cannot doubt that there are still not a few morbid [states which escape distinctive

recognition because their symptoms closely resemble those of diseases of common occurrence.

The present case clearly presents the characters of the condition known as syringomyelia, though it is exceptional in departing in some of its features from the commonly accepted type of the disease. Here I think it will be best for me to put forward briefly what is known of the morbid anatomy and pathology of this interesting affection. Cavities of various kinds are met with in the spinal cord as in other parts of the central nervous system. Thus a hæmorrhage, instead of becoming absorbed, may remain as a cyst or hæmatoma, and there may be a dilatation of the central canal of the cord as there may be of the ventricles of the brain, constituting a hydromyelia. The nature of the cavities in syringomyelia has not been thoroughly determined, but the trend of opinion is towards the view that they originate in a gliomatosis, or overgrowth of the neuroglia, which undergoes liquefaction in its central parts, so as to form one or more cavities with smooth walls, and containing a clear or turbid fluid. The cavities are formed in the grey matter in the neighbourhood of the central canal, with which they sometimes communicate, and they spread in various directions in the deeper parts of the cord, which may, in extreme cases, be converted throughout part of its length into an elongated cyst, so much of the nervous tissue as survives being crushed together in its walls. The change generally begins and is most advanced in the cervical region, but in exceptional cases, of which the present appears to be one, the brunt of the disease falls upon the lumbar enlargement.

The essential facts in the case of the patient I now show you are as follow :—

J. B., a labourer, æt. 54, began to suffer fifteen years ago from trouble about the feet which made walking difficult. Attacks of this kind recurred from time to time until they became continuous. The toes became strongly and permanently flexed and otherwise deformed, and six years ago some of the smaller ones on the right foot were amputated by a surgeon, but without any material benefit to the patient.

At the present time his condition is as follows : The general appearance is that of health, and the thoracic and abdominal organs are sound. The limbs, however, present several important departures from the normal.

Motor.—There is complete paralysis with wasting of the anterior tibial muscles, resulting foot-drop and flexion of the toes. A characteristic difficulty in walking results, the feet being raised too high and kept wide apart to enable the toes to clear the ground. The defect in walking is increased by the existence of extreme flexion at the first interphalangeal joint of the smaller toes, apparently due to shortening of the flexors. In the hands there is no obvious paralysis, but there is a similar deformity of the fingers, due apparently to shortening of the flexor profundus digitorum.

Reflex.—There is complete absence of the patellar and plantar reflexes.

Trophic.—As already stated, certain muscles are wasted. There is also marked change in the nutrition of the skin. When first admitted to hospital there were numerous small ulcers, apparently painless, on the lower part of the legs and the feet, and a purpuric eruption on the feet. These have healed to a considerable extent, but can still be recognised. A corn on one of the toes has ulcerated since he has been in bed in hospital.

Sensory.—Here the most characteristic changes are observed. In the region corresponding to the fourth and fifth lumbar and first sacral segments, that is, approximately, the whole of the legs below the knees, the sense of pain is almost gone. The prick of a pin causes little or no pain ; but the slightest touch is felt and correctly located. Throughout the same region the ability to distinguish heat and cold is quite lost ; a test-tube containing iced water touching the skin cannot be distinguished from one containing warm water. In the hands the only alteration of sensibility is some confusion of hot and cold sensations in the right middle and ring fingers.

The sphincters are normal.

The paralytic and other symptoms are somewhat more marked on the left than on the right side.

It will be noticed that the clinical picture, while pointing to some profound change in the nervous system, does not conform to that of any of the commoner affections. It bears some resemblance to multiple neuritis and to locomotor ataxy, but differs from both in certain essential points. In neuritis the progress would be more rapid and the disease would not last so long, there would be tenderness of the nerve trunks and muscles, and above all there would be no dissociated anæsthesia. Anæsthesia there might be, but all forms of sensibility would be pretty equally affected.

From locomotor ataxy the case is distinguished sharply by the presence of paralysis and wasting of muscles, a distinction which is confirmed by the absence of inco-ordination, of pain, of visceral symptoms, and of tachycardia. In this connection I should like to draw attention to what I consider the extreme importance of permanent acceleration of the pulse in the diagnosis of early cases of locomotor ataxy. I have at present five cases of locomotor ataxy, in various stages of development in my wards, and in all of them the pulse is persistently accelerated, being generally about 100 per minute, sometimes considerably higher. In the present case the pulse is usually between 60 and 70.

We will now consider the grounds on which is based the opinion that the case is one of syringomyelia.

Authorities are agreed that the characteristic indication of syringomyelia is the presence of a complexus of symptoms, all of which are present, in this case—symptoms which may be found independently in other morbid conditions, but which experience proves are never found in combination in any other disease. These symptoms are three—namely, loss of certain sensations, while others are retained ; the presence of paralysis, with wasting of muscles ; and trophic changes in the skin and other structures. Of these the most characteristic symptom, taken by itself, is the partial loss of sensibility—the "dissociated anæsthesia" of Charcot. Normally, we are conscious of three kinds of sensation in the skin—sensation of pain, of touch, and of temperature. In most conditions of impaired sensation all these

kinds of sensibility are lost in about the same proportion, but in syringomyelia it is otherwise. In this disease the sense of touch is generally normal in every respect, but the sense of pain and the power of distinguishing hot and cold objects in contact with the skin are more or less completely lost. This peculiar dissociation of sensation is not easy to explain; but in view of the pathological anatomy of syringomyelia, its occurrence lends colour to the hypothesis that the paths of the different kinds of sensation in the cord are not the same, and that sensations of pain and of temperature pass through the grey matter. The distribution of the anæsthesia corresponds to the segments of the spinal cord affected, and does not, as in the case of peripheral neuritis, correspond to the distribution of the sensory nerves. In consequence of the loss of sensibility serious injuries may be unnoticed by the patient, and to this some of the trophic changes are doubtless due.

The distribution and nature of the muscular paralysis are such as we might infer from what we know of the morbid anatomy. If the lesion is in the cervical enlargement, there will be paralysis, with wasting of the muscles of the upper extremity, corresponding to the spinal segments involved, and the muscles of the trunk and even of the lower extremity may suffer in succession. More common is it to find the lower limbs indirectly involved from pressure on the pyramidal tracts, there being no wasting, but spasticity of the muscles with exaggerated reflexes. A case of this kind might readily be mistaken for progressive muscular atrophy. When, however, as in the present case, the lesion is chiefly located in the lumbar enlargement, there is simply more or less paralysis of the muscles, with atrophy, loss of reflexes, and degradation or abolition of electrical response.

The nutritional disturbances in the limbs are of various kinds and may affect any of their structures. In the present case the smaller toes are much deformed, apparently from shortening of the flexor tendons and disorganisation of some of the joints; there is an indolent ulcer on the sole of the foot, reminding us of perforating ulcer; there are multiple ulcers on the leg, and a purpuric eruption on the feet. The stiffness and flexion of the fingers is, I feel sure, one of the manifestations of the spinal cord affection, though I do not find that such a condition has been previously described in this disease. A painless disorganisation of the larger joints, like that described by Charcot in locomotor ataxy, has been met with in some cases, and painless fractures have been described. The present case is exceptional in the advanced age of the patient, as well as in the locality affected. Though cases are occasionally seen late in life, the great majority of those recorded have been in patients under 40.

The progress of the disease is commonly, as in the present case, exceedingly slow. It may spread upwards to the medulla oblongata and so prove fatal, but as a rule it does not directly tend to shorten life.

The treatment must be symptomatic and palliative, since we have no means of influencing the processes at work in the spinal cord. It is thus on the same lines as the treatment of the commoner degenerations of the spinal cord. The absence of pain calls for vigilance on the part of the practitioner, since the patient, feeling no discomfort, may take no notice of more or less serious injuries, with the result that troublesome ulceration may arise and be the source of various forms of septic infection.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Malignant Epulis.

By Peyton Beale, F.R.C.S.

A man, æt. nearly 60, presented himself complaining of a large ulcerated mass on the right side of his hard palate; the growth looked as if it involved a considerable portion of the upper jaw as well. The history was of about three months' duration, but it was impossible to find out from the patient exactly where it started—*i.e.*, whether from the gum, from the tooth-socket, hard palate, or the upper jaw itself. From its appearance it was supposed to be an epithelioma starting in the palate. A small piece was removed, and on microscopical examination was found to be a spindle-celled sarcoma. The growth seemed to be adherent to the palate, and any attempt at stripping or peeling it off appeared hopeless. There was no evidence of any growth within the antrum. Mr. Beale said that the commonest form of malignant epulis was myeloid sarcoma, perhaps the next most common was squamous epithelioma, and this tended to involve the upper jaw and antrum extensively as a rule; he believed a spindle-celled sarcoma to be the least common form of malignant epulis. The history of these cases was generally that of the appearance of a small tumour at the edge of a tooth-socket, coming soon after the removal of a tooth, but there was nearly always a history of considerable damage to the alveolar process during extraction.

The case, Mr. Beale said, would be admitted to the hospital and operated upon. The operation he proposed to do consisted in making an incision round the growth on the hard palate, when the tumour, together with the mucous membrane, would in all probability be stripped off with ease; it would then be seen from which part of the alveolus the growth originally sprang, and this would be removed with chisel or cutting forceps. Care would then be taken to make sure that no part of the growth was extending up into the antrum.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Abdominal Operation for Traumatism.—Mr. Edred Corner operated on a little girl, æt. 5, who had fallen from a window on to some area railings, impaling her abdomen thereon. She had been brought to the hospital with most of her intestines prolapsed and exposed as she was carried through the street. On admission she had much shock, and was taken to the theatre as soon as possible. At least three-quarters of an hour had elapsed in bringing her up to the hospital, &c., before the operation and all the while her intestines were prolapsed. The intestines and skin were cleaned up with as much saline as was possible. Four rents in the bowel and two in the mesentery were sewn up with silk. After further washing with saline, the intestines were returned to the abdomen. Whilst repairing the abdominal wall it was found that the left rectus has been completely torn across. The peritoneum was sewn, then the rectus, then both recti sheaths, which were torn extensively and transversely. As a precautionary measure the child was given three

doses of anti-colon serum. The abdomen was no washed out. Mr. Corner said that the interesting points in this case were: (1) The severity of the injury in one so young; (2) when a bowel is ruptured the rupturing force seems to paralyse it, so that little or no fæces are extravasated; (3) the necessity to hunt up and see to all of the many injuries and overlook none; (4) in one place the bowel was separated for an inch and a half from its mesentery, but it did not seem to have suffered much in spite of being so separated from its blood supply; (5) the giving of the anti-colon serum in anticipation of an infection with the colon bacillus would, he thought, contribute to a successful result; (6) it was, he considered, better to make no attempt to wash these cases with soap and water or any antiseptic, but to depend on the mechanica action of flushing with normal saline; chemicals injure the peritoneum, impoverishing its resisting power to the onslaught of organisms which must be present after such an injury.

It is satisfactory to state that after two or three days' illness the child became quite convalescent. Mr. Corner thought that the two or three days' illness indicated some infection by the colon bacillus which, as he had predicted in No. 5 of his points of interest, had been successfully combated by the giving of the anti-colon serum.

ROYAL FREE HOSPITAL.

CHRONIC ABSCESS OF THE BREAST.—MR. J. P. LEGG operated on a woman æt. 43. The patient stated that for five weeks she had noticed an aching pain in her left breast. Previous to this time she had been quite well. The nipple was a little sore at the time, but it soon got better. During the next ten days the pain got worse, and a lump about the size of a marble was discovered. It had steadily been increasing in size, and getting harder. Two swellings had also been noticed in the left axilla, and three weeks after the onset of the symptoms the skin over the breast became red and œdematous. There was no history of injury. the patient was a married woman, the youngest child being thirteen years of age. On examination the patient was exceedingly stout. The left breast was about half as big again as the right. She stated, however, that it had always been slightly larger than the right, but recently much more so. The skin over the whole breast was red, infiltrated and œdematous; the subcutaneous veins were slightly larger on the left side. On palpation a tumour as large as an orange was felt just above the nipple. It was very hard and had rather an irregular surface, the edge being fairly well defined. The skin dimpled on trying to slide it over the surface of the tumour. There was no discharge from the nipple, which was healthy. There was very little local pain.

In the left axilla some small hard glands could be readily detected. The right breast was normal. An exploratory incision was made into the mass and a large quantity of pus escaped. The abscess was found to occupy the centre of a dense mass of hard tissue, and therefore the whole swelling was removed by dissection for further examination, care being taken to cut wide of the walls of the abscess and to include a considerable amount of the adjacent breast tissue and fat. A drainage tube was placed in the upper part of the incision which was closed by interrupted sutures. Mr. Legg said that this patient illustrated exceedingly well the difficulty in diagnosing breast tumours. Here was a woman with a hard, painless tumour presenting many of the local signs of carcinoma. At the same time there were present some of the signs of inflammation, viz., the redness and persistent œdema of the skin and a tumour. The diagnosis lay between an inflamed, rapidly-growing carcinoma and an abscess. There was, he thought, no very obvious cause for an abscess, and the local signs were not suggestive of tuberculosis of the breast. Delay in the case of any tumour of the breast, he pointed out, was always contra-indicated. If the tumour was a carcinoma the sooner the patient was rid of it the better would be her chances of recovery. If the tumour turned out to be inflammatory, the sooner would she recover. Therefore, in the present case, it was decided to find out the nature of the swelling by making an incision and cutting out the mass. Until the mass was actually removed, its inflammatory nature was not clear. The walls of the abscess were so dense and hard, the possibility of a carcinomatous growth being present could not be excluded till a section was made. After removal the mass appeared to be inflammatory, it had a glistening white appearance, and this was confirmed subsequently by the microscope. All tumours of the breast, whatever the age of the patient, should be removed, he considered, and a careful microscopic examination made. For experience shows that cancer is not very uncommon in patients under thirty years of age. On examining the mass removed, it was found to consist of a cavity 1½ inches in diameter having a lining membrane of granulation tissue, the walls of the cavity being composed of dense fibrous tissue fully one inch thick. Microscopical sections did not show any evidence of malignancy. The adjacent breast tissue showed extensive chronic inflammatory changes. The patient made a good recovery, and left the hospital at the end of ten days.

FRANCE.

Paris, Aug. 19th, 1906.

CHRONIC RETENTION OF URINE.

CHRONIC retention of urine arises from different causes: (*a*) bladder (paralysis of medullary origin, vesical sclerosis); (*b*) urethra (stricture, gonorrhœal or traumatic); (*c*) periurethral (compression in woman from pregnancy, fibroma, pelvian kysts); (*d*) prostate (compression by the lateral lobes of the gland).

In all these cases, says Prof. Legen, the bladder struggles successfully for a time, but finally the vesical muscle yields and retention is the result, and of which there are three types—incomplete retention with distension, incomplete retention without distension, complete retention.

The first-named is the gravest and the most difficult to treat. A large quantity—frequently a quart—remains in the bladder, although the patients urinate night and day. The urine is limpid and aseptic. Another consequence of this incomplete retention is an abundant polyuria. The patients urinate as much as four quarts a day, and are seized with great thirst. Dyspeptic symptoms set in as the consequence of renal insufficiency, which always exists at the same time. The tongue is dry, and vomiting is frequently present. Locally the bladder is found enormously distended, presenting the form of a large and smooth tumour. The position of the patient is grave, both the ureters and the kidneys are distended with probable renal insufficiency as the result.

Every antiseptic precaution should be taken in treating such patients, as infection is imminent.

The urine should not be completely drawn off, otherwise hematuria might be provoked, followed by coma and death.

The therapeutical indication is to diminish the tension of the bladder progressively. The catheter (coudé) should be passed twice a day and a pint only of liquid drawn off. At about the end of a week or ten days the bladder may be completely evacuated and four ounces of a solution of nitrate of silver (1 in 1,000) injected. The catheter should not be left *in situ*.

If by chance hematuria occurred, the pressure in the bladder should be re-established by injecting six or eight ounces of a solution of boric acid. If in spite of precautions taken the temperature went up, the catheter should be left in permanently for four or five days, but plugged, and the patient recommended not to withdraw the plug more than two or three times daily, and only allow a pint of urine to escape at the one time.

Incomplete retention without distension requires a different treatment.

In such cases the urine stagnates, leaving in the bladder a residue of four or five ounces. The signs of this retention are as in the preceding case, incontinence. It is not rare to see patients urinate a quart in the night. The patients become wasted, pale and suffer from, troubles of digestion. Such persons have been more than once treated for cancer of the stomach. If the urine becomes infected, fever sets in in a remittent form. The malady may last years, but it exposes to vital and local danger renal infection and sclerosis of the vesicle muscle.

The treatment varies with the cause. In case of stricture, internal urethrotomy should be performed and where the prostate was at fault it should be removed if the condition of the patient permitted, otherwise the catheter should be employed three times a day, followed by antiseptic injections.

These patients can live a long time, provided they are properly treated.

Complete retention is the inevitable accident waylaying all patients with hypertrophied prostates. Not being able to urinate without a catheter, these patients relieve themselves at every moment without any regard to cleanliness. They carry their catheters in their pockets, and wet them with saliva to make them pass. Infection is frequently the result of this ignorance of antiseptic rules.

The treatment of complete retention consists in the use of the catheter as often as necessary with washing-out of the bladder. Where possible, prostatectomy should be practised; it allows the vesical contractibility to return, although the vitality of the muscular fibres seemed to have been compromised by years of retention.

Treatment of Burns.

Bathe the parts first with
Picric acid, 1½ drachms;
Sterilised water, 1 quart.
Then spread on salol gauze the following ointment:—
Stovain, 10 grains;
Salicylic acid, 1 drachm;
Dermatol, 1 drachm;
Ess. of thym., 5 mm.;
Vaseline, 4 ounces.
The ointment should be diluted with oil of sweet almonds if the burns are extensive.

GERMANY.

Berlin, Aug. 19th, 1906.

Diseases of the Blood.

At the Society for Innere Medizin, Herr Mosse spoke on this subject. He said the normal anatomy of bone marrow from the 14th to the 16th year showed a network in the meshes of which fatty tissue was embedded, whilst the nodules were cells containing hæmoglobin, and others free of it, the latter with few granulations (basophile, neutrophile and eosinophile) and the lymphocytes. These large cells with basophile protoplasm with commencing formation of granulations and large nuclei, the so-called megaloblasts of mother cells. These large bone marrow cells, with neutrophile protoplasm, of the significance of which we were in ignorance. The hæmoglobin containing cells and those free from it sprang not in common from the megaloblasts, but as the red blood corpuscles as well as the white originated from themselves, there were various stem cells present.

We were acquainted with only circumscript and diffuse diseases of the blood. To the first the myeomata belonged; in these were found erythrocytes, lymphocytes, and myelocytes.

Among the diffuse diseases was pernicious anæmia, with polycythæmia and change of some cell forms (megaloblastic degeneration of bone marrow). Then ordinary anæmia and chlorosis; here there was no definite characteristic condition in the bone marrow.

Then the diseases of the white blood corpuscles; increase of the neutrophile polynuclear cells; increase of all other cell groups in myelogenous leukæmia. The diseases of other organs consisted in the passage of myelocytes through the circulation and consequent metastasia in the organs. In contrast to those conditions was the increase in the lymphatic portion of the bone marrow, the lymphocytes—lymphatic leukæmia. In pseudo-leukæmia there was an almost normal condition of the blood, only some increase in the lymphocytes. There was also, however, a myelogenous pseudo-leukæmia with megaloblasts. After anæmia an aphasia of the bone marrow took place.

Treatment.—Anæmic and chlorotic cases were generally treated wrongly; we did not allow them to rest sufficiently. A longer rest in bed assisted very much.

Pernicious anæmia demanded a hygienic, dietetic therapeusis. In leukæmia the X-rays were to be used, through their use the sources of the cells degenerated.

At the Freie Vereinigung der Chirurgen, Exz. Bergmann related a case of

Operation for Diverticulum of the Œsophagus.

It was the first opportunity of the kind he had had since 1887. The patient who was sent to him with the diagnosis "struma" had a tumour on the right side of the neck, which as she herself observed, swelled on eating, and was emptied by pressure. On sounding the œsophagus, the sound constantly passed into the diverticle; only once did it pass direct into the stomach. After giving bismuth porridge, the diverticle was plainly visible through the X-rays. By this a correct notion of the size and situation of the diverticulum was obtained before operating. The sac was readily peeled out and the sutures readily applied. The wound healed so readily that the patient was able to swallow food on the fifth day.

Herr Sticker spoke on

Recurrence in Carcinoma.

He first discussed the question whether carcinoma could be propagated by implantation, and declared that it could. That carcinoma was transmitted by transplantation of cancer cells was no longer doubted. Spontaneous implantation and post-operative implantation were not the same.

From experiments made with a specially transmissible sarcoma from the vulva of a bitch, he had arrived at the following conclusions:—If several germs were implanted into an organism several grew. If carcinoma was already present at one spot and a second germ was implanted at another spot, the implantation would not succeed. If the first tumour was extirpated, the implantation at the second spot would be successful. If a portion of the first tumour was left behind, this would grow, and implantation at a second spot would be unsuccessful. The cause of this peculiar behaviour he believed to be that in the immediate neighbourhood of the tumour there was a zone of toxines, whilst further away was that of the antitoxines that rendered a successful implantation of germs impossible.

From the experiments made it followed that inoculation carcinoma originated more readily when, in operation, all disease was completely removed, than when such removal was incomplete. In any case the experiments taught that there was a possibility of setting up inoculation carcinoma during removal of the disease, that this should be kept in mind, and that the rules for avoiding such an occurrence given by Winter, among others, should be observed.

Herr Newhaus said that from his own experiments he was inclined to believe that inoculation carcinoma was often in reality multiple carcinoma, and he thought the experiment carried out by the giver of the address being made with a peculiarly infectious tumour did not quite afford any positive proof.

Ecz. v. Bergmann observed on this point that multiple carcinomata were exceedingly rare occurrences.

AUSTRIA.

Vienna, Aug. 19th, 1906.

PYOCYANINE IN LA GRIPPE.

ESCHERICH at the Gesellschaft gave his experience of B. pyocyanine in the treatment of nasal catarrh, etc. The drug was a powerful bactericide and disinfectant. Properly it may be designated a proteolytic enzyme, which Emmerich and Löwe have named "Nukleasn," obtained from B. pyocyaneus by a sort of autolytic process in the protoplasm. This new substance, by whatever name, has the power of acting locally as a powerful disinfector. Escherich has used this preparation since autumn last in the form of a spray with wonderful success. He is not satisfied that it will destroy the diphtheria bacteria in the fauces, but it certainly destroys all the catarrhal forms in the fauces, and is therefore an excellent local disinfector. Pfeiffer's micrococcus catarrhalis is destroyed in the fauces by five drops of pyocyanine passed in through the nasal cavity. Meningo-coccus disappears from the throat with the same rapidity when the preparation is used. This has led to the conception that injections of pyocyanine into the cerebro-spinal canal would modify or evert meningitis. Following this train of argument, Escherich commenced intradural injections of three to five cubic centimetres of pyocyanine, with a decided diminution in the intensity of the disease, and complete disappearance of the meningo-coccus from the cerebro-spinal fluid when withdrawn by the aspirator. It often occurs that when the meningo-coccus disappear from the nasal secretions the meningitis is everted and the child escapes from this fatal disease.

FIBROMA OR GLIOMA IN CORD.

Erben presented two cases with paralysis of arms from different reputed causes which often lead to confusion in diagnosis. The first was attributed to wearing a strap over the arm in carrying his case of tools. One day he was more loaded than usual when one of the straps gave way over the left shoulder, allowing the heavy case to swing round, locking the right shoulder and unduly pressing the clavicle against the spinal cord and first rib, and crushing Erb's point as well as the plexus in the arm-pit. Four days after this accident the right arm fell helplessly by the side. The brachical plexus seems to have been involved. The triceps, radial nerve, and later the pectoralis were quite obsolete. Here it appeared we had peripheral combined with the central paralysis tending to confuse the issue.

In the second case the paralysis commence gradually in the neck and shoulder muscles on both sides of the body, as well as the upper parts of the right arm. The paralysed muscles had a fibrillary movement, pointing to the anterior horn of the cord, resembling the humero-scapular type. There were also contractions of the upper arm of the "Primâre" nature, indicating a central irritation in the motor centre. From the loss of muscular power, it was strong proof that the roots in the cord were primarily affected. No bone or meningeal defect could be observed or suspected and therefore left no other positive result than some intramedullary growth or morbid change. This case was three years under observation and very little change could be perceived, which demonstrates the slow growth and the suspicion that the change was due to tubercle, fibroma, or glioma, but probably the latter lying somewhere between the second and eighth segment of the cervical region.

CERVICAL FORM OF SYRINGOMYELITIS.

Flesch records a very interesting case of syringomyelitis, commencing eight years ago with the loss of feeling in the left hand for cold. The patient was a merchant, æt. 28, who was early affected with atrophy of the muscles of a central character. Half a year ago the skin was covered by a form of ichthyosis or accentuated psoriasis more severe over the extremities. After two months the psoriac patches began to fall off, leaving brown pigmented patches not elevated, nor thickened, but having a normal sensibility. The histological examination proved the absence of any parasitic origin.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

COMPLIMENTARY RECOGNITION OF SIR A. R. SIMPSON.—By way of public recognition of Sir Alexander Russell Simpson's work and worth it has been resolved to raise a fund for the endowment of a bed in the Maternity Hospital, for which a sum of £1,000 will be required. A large and influential committee has been formed for this purpose, the chairman being Baillie W. S. Brown, Edinburgh, while among the vice-chairmen are Lord Overtoun, Sir William Turner, Sir John Halliday Croom, Dr. Playfair, Mr. Macgillivray, Dr. Affleck, Dr. Berry Hart, Dr. Ballantyne, and Dr. Ritchie. In their appeal the committee believe that the opportunity of showing this appreciation of Sir Alexander Simpson will be welcomed by practitioners in other lands and in our own land who remember him as a gifted teacher and a kind friend, by many who have grateful remembrance of his skill, by his fellow-citizens, his comrades in Christian service, as well as by others belonging to a wider circle. It is felt that this appreciation would not be appropriate to the character of one whose life has been a signal example of unselfishness, unless its primary purpose were to confer a benefit on others, especially on the poorer classes. Any sums contributed beyond what is necessary for the endowment of a bed will be used in making a personal gift to Sir Alexander and Lady Simpson, or in such a way as may be agreeable to them. It is hoped that the presentation will be made early in October, as Sir Alexander Simpson proposes about that time to visit mission stations in India and China, and afterwards to attend an important Christian conference in Japan. Contributions to the fund may be sent to Mr. John Nicholson, manager of the Clydesdale Bank, George Street, Edinburgh.

BELFAST.

"TEMPERANCE SUMMER SCHOOL" AT PORTRUSH.—A new movement in the interests of temperance reform has been started this year in the shape of a conference, or "Summer School," which has been held during the past week at Portrush. At the opening meeting the chair was taken by Miss Richardson, B.A., one of a family which has been for years identified with temperance and social reform at their model village of Bessbrook, co. Armagh. For four days there were frequent meetings, and a number of lectures and addresses were given on the scientific and social aspects of the temperance question, several medical men taking part. On the first day Dr. Watson, of Bloomfield, Belfast, read a paper on "The Handy Drug." He dealt specially with the common use of alcohol as a household remedy for all the ills that flesh is heir to, and argued that this was often the foundation of a taste for alcohol which produced disastrous results in later life. At the

best, he believed it to be a drug of doubtful qualities and many dangers, and he longed for the time when only the curious antiquarian might be heard to ask, "What is whisky?"

On the third day Major Jackson, R.A.M.C., Cork, gave an address on "Temperance in Relation to Hygiene." He spoke specially of individual responsibility for the improvement of our sanitary surroundings, which we are too much inclined to leave to the State or municipal authorities, and among such personal efforts he placed the promotion of temperance in a foremost place. On the same day, Dr. Norman Barnett, Belfast, read a paper on "Temperance Legislation from the Medical Standpoint." He said he wished to discuss, not those acknowledged insane as the result of alcoholic excess, but the chronic "drunk and disorderly." He pointed out the effects of alcohol on the white corpuscles of the blood, and on nerve tissue, and said that as a result of long indulgence these cases became incapable of keeping themselves clear of alcohol. They were usually given short terms of imprisonment, as if they were reasonable beings, but he argued that recent research had shown that their nerve cells were so degenerated that they could not be considered as such. An injustice was thus done, not only to the man himself, but to the State which had to support him, and to those dependent on his support, who might have to fall back on State support also.

On the closing day, those attending the "school" were hospitably entertained by Lord Macnaghten at a garden party at his beautiful place, Runkerry, close to the Giant's Causeway. The movement seems to have been a great success, and will no doubt be repeated another year.

Public Health.—The Public Health Committee of the Corporation has come to the conclusion that gentle persuasion has failed to prevent people throwing waste-paper, orange and banana skins, broken glass, &c. in the street, and they have therefore drawn up a code of bye-laws for the better prevention of such nuisances. The idea is excellent, if only the bye-laws are enforced, but past experience leads us to fear that their publication will afford some occupation to printers and bill-stickers in the dull season, and end there. An outbreak of typhoid in the south side of the city, in one of the best and supposed most healthy residential districts, has caused some anxiety. So far the cause of the outbreak has not been traced.

Larceny from Queen's College.—A porter of the Chemical Department at Queen's College has just been committed to prison for four months for the theft of a quantity of platinum. He abstracted some small vessels entire, but the larger ones he simply pared down round the edge, rendering them a little shallower. It is easy to see that such a process, carried to a moderate length only, might prove very hard to detect. The total quantity taken in this case seems to have amounted to about £70.

LETTERS TO THE EDITOR.

THE SUPPRESSION OF QUACKERY.

To the Editor of the Medical Press and Circular.

Sir,—The letter of Mr. Henry Sewill, published in your issue of August 15th, contains a munificent offer, and it is to be earnestly hoped that others may come forward in the same way. Might I suggest the opening in your columns of a subscription list to help? Mr. Sewill's object is a great one, it is to suppress every form of quackery. I have done my best to aid in the suppression of one special branch of charlatanism—the aural quack. Recently a series of most disgraceful advertisements appeared in the *Daily Mail*, in which a well-known and oft-exposed aural quack, "Professor" Keith-Harvey, laid ingenious traps for deaf sufferers. After repeated letters to the Editor I at length succeeded in getting these "ads." suspended during investigations. I was able to help the latter by the ready assistance of the Editor of *Truth* and Mr. Evan Yellon, the author of "Surdus in Search of his Hearing," one of the best and most courageous of exposures of aural quackery ever made. The Medico-Political Committee of the British Medical Association are taking this Keith-Harvey matter up, and I hope it will be able to achieve something.

What is wanted, however, as Mr. Sewill points out, is a stringent law, rigorously executed, and if professional apathy could be overcome, doubtless such a law could be obtained. I would further suggest that the Medical Press and Circular should draft a petition, confined to the medical profession, asking for a Royal Commission.

The absurd discussions upon matters medical which we see every day in lay papers help the quacks largely. As an instance, I would quote the half column of fervid nonsense in a reputable paper to-day, stating that a "well-known medical specialist" says that motoring will do away with kissing. Personally, I do not believe that any medical man in the United Kingdom would make such an absurd statement and my unbelief is strengthened by the following fact:—Last year I was consulted by a journalist working for this very paper. In the course of some general conversation, I asked him if he could tell me who the "well-known Harley Street specialist" was who was so fond of airing his views in the paper in question. He laughed, rubbed his hands, and said, "It's mostly *me*."

It may interest your readers to know that the "Drouet Institute" people, so thoroughly ruined by *Truth's* "ruthless exposé," have started operations again. They have taken a place in New Oxford Street, and have re-named themselves "Aural Clinic, Ltd." I am communicating this fact to *Truth*.

I am, Sir, yours truly,

Macleod Yearsley, F.R.C.S.
Senior Surgeon to the Royal Ear Hospital.
10, Upper Wimpole Street, S.W.

To the Editor of the Medical Press and Circular.

Sir,—Twice within the last year or so—once within the last few months—one of the most widely advertised of the quack medicines of the day has been denounced by Judges of the High Court as an impudent fraud. Advertisements of this nostrum, which, after the last trial ceased for a time to appear, have now again begun to be published in the leading London papers. It must be assumed that the astute men of the world who own, edit, and manage the journals in question are not aware of the character of the trade which is being carried on, and can be successfully carried on only with their help. These censors of political and private morality would no doubt be amazed, shocked, and confounded if made to realise their position in this matter. If quackery is to be suppressed the first step must surely be to enlighten these gentlemen and the intelligent public with regard to its nature and effects. It ought not to be beyond the powers of our profession, acting together, to bring the facts into the light of day by means of a Parliamentary Commission or otherwise. If the men who hold leading positions will come forward there need be no doubt about the backing they will command from the bulk of the profession.—I am, Sir, yours truly,

An Obscure Practitioner.

August 15th, 1906.

To the Editor of The Medical Press and Circular.

Sir,—I always admire a man who is willing to back his opinion by practical support. Your correspondent, Mr. Henry Sewill offers to subscribe £50 if ninety-nine others will contribute a like amount as a nucleus for organising and presenting evidence before a Royal Commission for the suppression of quackery. I might not be able to subscribe so large a sum myself for the benefit of the many, but should be glad to contribute towards so desirable an object. I fear, however, it will be considered by some as "utopian," and by the majority of the profession as "not their business."

Personally, I do not agree that it is not our business to protect an ignorant public from the cruelty and rapacity of quacks, but the great majority of us have in the past so persistently ignored our common interests and disregarded the entreaties "to move," when urged by the energetic appeals of yourself and the editors of other medical media, that I for one despair of the chances of success of your correspondent's effort for the suppression of quackery.

I am, Sir, yours truly,

J. WILSON.

August 15th, 1906.

THE TREATMENT OF PHTHISIS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Does it not appear reasonable to most of your readers that we must look to climate as more important than any other therapeutic agent in the treatment of phthisis? Those who have had opportunities of judging of the influence of climate would be conferring great benefits if they would give the results of their observations to the profession, through which the public would derive so much benefit. There are many in this country who would do well to leave us for one of our great Colonies—Canada, Australia, or New Zealand. We cannot change the climate of our own country, and it is probable that very little, if any great change in the mortality from phthisis will be obtained from any of the many new plans that have been brought forward lately for its relief.

Our population is increasing to such degree that emigration must be looked to more than anything else to relieve it, and it would be well if some guidance could be given by the profession to those who are anxious to leave us, and find a country where the climate would make their lives useful and contented. There is some fine climate in Australia along its Southern coast, or in the north island of New Zealand, while Canada is a country which offers various and great advantages in the matter of health. Might I suggest that your columns may be the medium of widening our knowledge of what our Colonies offer in respect to health, and that the present state of ignorance may be changed to one of accurate and reliable knowledge for the great good of many.

I am, Sir, yours truly,

ROBERT LEE.

THE FALLING BIRTH-RATE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The birth-rate in England and Wales continues to fall steadily. During the three months ending June last the rate is the lowest recorded in the second quarter of any year since the establishment of civil registration, and is 1·6 per 1,000 lower than the average rate for the corresponding three months of the ten years 1896–1905. This subject, as it deserves—has formed a frequent theme for editorial discussion, and has from time to time excited animated controversies in your columns. The fact seems clearly established that the fall in the birth rate is not due to natural causes, but to the deliberate action of married couples in preventing conception. This fact was also proved in the enquiry carried out by the Government of Victoria, Australia, a year or two ago. It is notorious that the stagnation of population in France is due to the same cause, and it is not doubted that the diminishing birthrate in most of the other countries in Western Europe and in the United States is being brought about by similar means. Whatever may be the ultimate effect upon the moral and physical development of the race there can be no doubt that empire will depend upon population, and that nations in decay are at this epoch as surely doomed to be gradually supplanted or conquered by more virile races as they were in the old days when the barbarians came down upon Rome. For thirty years the population of France has remained at 38,000,000, a much smaller number than there is room for on her fertile soil, and she has no men to send to vast oversea possessions, misnamed Colonies, which she has in later years acquired. On the other hand, Germany has 61,000,000 in the Fatherland, and her numbers are increasing by nearly a million a year. The whole British Empire, as has been lately pointed out, contains only 55,000,000 of people of white or European blood. If we do not become prepared to people our Colonies, is it likely we shall be allowed for ever to hold them? With the example of France before us, and with this exemplification of the rapidity with which a great people can deliberately and out of pure egoism destroy its position among the imperial powers, it must be admitted that the population question calls for the serious consideration of our statesmen, and of all those who believe that the establishment of a truly mighty British Empire is necessary for the continual advancement of the whole world along the paths of high civilisation, along which, as we flatter ourselves, we have already made such notable progress.

I am, Sir, yours truly,

August 16th, 1906. IMPERIALIST.

ETHICS IN PRACTICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have always had a keen admiration for the manner in which your paper upholds the ethical purity and the dignity of our profession. We are living in an age of strenuous competition, and I am afraid that the result is a lowering of our ethical standards. We must win over to our confidence the laity; we must impress upon the public our own personal merits, and, still more, the demerits of our colleagues. In a word, we must "go one better" than our colleagues. Now, if this meant that we intended to excel by devoting more time to the study of our work, and so leave the laggards behind, I should be the last to complain. Unfortunately, this is not the case. It is a case of snapping another man's patients when the other man has his back turned, and saying nothing about it: or, as in the case upon which you comment, adding a string of meaningless letters, such as M.B., B.A., after your name, meaningless to the members of the medical profession, but possibly full of meaning to the laity. With you I hope and trust—as many other right-minded members of our profession also hope—that the local medical men of the town in which this member resides will act promptly and energetically, and will teach him that he belongs to a noble profession, the majority of the members of which will not tolerate such behaviour. Have we not been pouring out the vials of our wrath upon a more or less uneducated class of women who, in ignorance which is pitiable, flaunt after their names such letters as L.O.S., C.M.B., in the hope of deluding their too often ignorant victims into the idea and belief that they hold some medical qualification?

It is high time after such declamations against those who are outside our profession, that we begin to review the conduct of our own colleagues, and, having so glaring a case of the assumption of meaningless letters as the one mentioned in your current issue, that we prove to the medical world and the world at large that we shall not tolerate such snobbery in our ranks, and remind offenders that *magna est veritas et prevalibit.*

I am, Sir, yours truly,

SPES.

CREATED ABSCESSES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The reading of your Paris correspondent's article on above subject reminded me of this case, which happened some years ago: A prepossessing young lady, about eighteen or nineteen years of age, had a large-sized gland, hard and fixed, in side of neck. Her father brought her for my opinion, as he was told "it must be cut out." I reasoned, if I could turn the gland into an abscess, and, when ripe, let out the contents by small incision or aspiration, the neck would show no ugly mark. I told the patient, if she could bear pain

well. I would try and cure the "lump" without cutting. I injected a hypodermic syringeful of spts. turpentine (and the pain produced was so severe I rather regretted having done so, but prescribed hypnotic to be taken regularly to keep pain in check, and hot poppy-head and cammomile stupe to be used each night before retiring). In about a week abscess was ripe, and I evacuated the contents—about eggcupful. No mark visible after a few days. Having seen the good results in this case, I tried it in another, with equally successful ending. The only two cases I have treated; and as two cases could not prove much I should not have written but for seeing your correspondent's remarks. I should think in cases of tubercular glands, the injection of turpentine or spts. ammon. aromat. would produce abscess without risk, and leave little or no mark when opened by small incision.

I am, Sir, yours truly,

Alexander Duke.

London, W.

SYPHILIS AND TUBERCULOSIS.

To the Editor of the Medical Press and Circular.

Sir,—There is a singular attraction for some of us in the study of disease, as one of the most active and injurious forces that influence the development of human life and happiness.

From what source any disease may spring, and how it may act on the human species, may take up the whole thoughts and spare time of some of us, and, probably, no scientific problems bring more satisfaction, when solved than the discovery of the nature and origin of any disease which has inflicted suffering, and the prevention of which is the means of saving human life.

In carrying on this kind of investigation we must be careful to keep our minds clear of theory in every form, and by theory I mean the influence of imagination, and errors of observation.

Some of us are working for what we call principles; some of us are contented to accumulate facts, and leave these alone till they have arranged themselves in some order, and work out their own laws or principles for themselves.

The chief object that I have in writing this letter to you is to consider the last paragraph in the lecture that was published in the Medical Press and Circular of August 8th, and was given by Mr. Hutchinson at the London Hospital on the Connection between Tuberculosis and Syphilis. In that last paragraph Mr. Hutchinson tries to lay down certain "principles"; and as I think these are not founded on facts, they ought not to be allowed to influence those who are engaged in the practice of our profession.

As far as I can conceive of what is meant by the word 'principle" in scientific work, I should say we mean what in mathematics or physics we should call a "law" or "theory."

What Mr. Hutchinson wants to lay down as a principle is that if any one has a tendency to tuberculosis, and then is infected with syphilis, the consequences will be modified, that is to say, the symptoms, &c., will probably differ from those which would be observed in a case where there was no tendency to tuberculosis.

Now, in regard to hereditary syphilis, no evidence can be brought forward in support of any definite opinion on the question; Would a tuberculous infant who inherits syphilis show any different symptoms from those where the child did not inherit tuberculosis? Syphilis is not a definite disease, for the simple fact stands out as clearly as possible, and of this Mr. Hutchinson seems either to be ignorant or unable to understand. The syphilitic symptoms vary in infants and young children according to the state of the father's or mother's health at the time of conception, that is, the stages through which the syphilitic infection had passed. I tried to put before the profession some years ago in the lectures I gave at the Great Ormond Street Hospital, and which were published in the Medical Press and Circular, the results of many years careful study of infantile syphilis. Between 700 and 800 cases passed under my care and I allowed no "theories," and no "principles" to influence me in the study I was pursuing.

If Mr. Hutchinson had impressed upon the students at the London Hospital that syphilis is not a definite constant like variola or scarlatina, it would have been far better than to tell them what is not true, that "the virus, in all probability is always the same." He might have told them how Dr. Cory fell a victim to this error, and how he vaccinated himself with syphilis. Dr. Cory was an old friend of mine, and I was indeed sorry that his ignorance or wrong "principles" led him into such sad trouble. He and Mr. Hutchinson and John Hunter and many others somehow are always under the influence of theory, and won't look at facts that go against them.

I am, Sir, yours truly,

Robert Lee.

OBITUARY.

W. J. MARTIN, M.D.

Much regret has been caused in Dublin by the death at his residence of Dr. W. J. Martin, of Harcourt Street, an old and very highly-esteemed member of the medical profession. Dr. Martin was the son of the late Mr. James Martin, Cappagh, County Dublin, and brother of the late Sir Richard Martin, Bart., of Merrion Square. Dr. Martin, who was connected with Jervis Street Hospital for close upon fifty years was qualified physician at the age of 21, and amongst the appointments which he held were Inspector of Anatomy for Ireland, Surgeon to Richmond Asylum, and Fellow of the Royal Academy of Medicine. At the last meeting of the Committee of Management of the Richmond Asylum, the following resolution was, on the proposition of the Chairman, carried unanimously:—"The Joint Committee of this Asylum have learned with unfeigned regret of the sudden demise of Dr. W. J. Martin, Visiting Surgeon, an old and loyal officer of the Institution. During his long service of twenty-five years he enjoyed the warmest esteem of the Board and staff of the Asylum, his amiability and kindness to the patients securing him an affectionate regard. We wish to convey to Mrs. Martin and family this expression of our sincere condolence." The Chairman also referred sympathetically to the fact that Dr. Martin had been on duty the day before his death.

A. E. CURTIS, M.B., C.M. Edin.

We record with sorrow the death at Cheadle, near Stockport, on August 11th, of Dr. A. E. Curtis, formerly of Sheffield. He was 43 years of age. For a number of years he was in partnership with Dr. Reckless, at Broomgrove Road. Five or six years ago Dr. Curtis took up practice at Infirmary Road, but in May last year an unfortunate illness necessitated his retirement. Latterly he removed to Cheadle. A more kindly, generous and attentive medical practitioner there never was, and the appreciation of his worth and good nature went far beyond his professional sphere. He was interested in sport and was frequently to be seen at football and cricket matches. In musical circles his severance from Sheffield was keenly felt. He possessed remarkable vocal powers, and was a valued member of the Choral Union.

At the half-yearly court of governors of the East London Children's Hospital, Shadwell, it was reported that a donation of £3,000 had been received from the Zunz trustees and a legacy of £7,000 under the will of the late Mr. Thomas Crockett, of Droitwich.

REVIEWS OF BOOKS.

INTERNATIONAL CLINICS (*a*).

THE present volume of this quarterly journal contains as usual a number of papers and clinical lectures on therapeutics, medicine, surgery, pathology, and some of the medical specialities. Most of them are interesting and readable, but are only of ephemeral interest, but a few of them deserve more than a passing attention. Out of the twenty-five separate contributions which make up the volume the most valuable in our opinion is that by Dr. Corner, of London, on Post Operative-Neurasthenia. The condition to which he calls attention must be familiar to all surgeons and physicians in large practice, but up to this only one or two have taken the trouble to point out its existence, while many surgeons we believe are accustomed to dismiss, more or less contemptuously, those patients who still complain of unpleasant symptoms after the cause of such has been apparently completely removed, forgetful of the fact that they have been dealing with a living body and not with a physical machine. To such surgeons we strongly recommend this paper. In it Dr. Corner points out that the neurasthenia phenomena may exist in very different degrees, and also remarks that many patients should be studied carefully with reference to their nervous equilibrium, before any operation is undertaken except in cases of absolute necessity. The severity of the operation is not the only thing to consider, for in many individuals the dread of an anæsthetic may prove more potent for ill than even the fear of the knife and the subsequent pain. As a fact Dr. Corner has observed typically neurasthenia symptoms after such simple procedures as hernia operations, as well as after more extensive operations. Another paper to which we would claim attention is that by Dr. Warkin on the Effects of X-Rays upon the Blood-Forming Organs. This is a subject which has lately attracted a great deal of attention, and it is here dealt with in a most comprehensive manner. The paper in fact constitutes, we think, the most complete summary of the subject as far as present knowledge goes, in the English language. A second interesting contribution under the section in Pathology is that on Eosiniphilia, by Charles Simon. The paper is historical as well as experimental, and brings together most of the accepted knowledge on the subject, as well as adding one or two new points. Space forbids us to do more than mention the paper on "Cysts of the Lesser Peritoneal Cavity," and that on "Post-Tussive Suction." Both are interesting and suggestive and, along with those already mentioned, make the volume well worth purchasing.

VOLUME I. of the sixteenth series of International Clinics, contains, as is customary, a review of the progress of medicine and allied sciences during the past year. This is, we think, its main claim to be of value, and we may at once state that in our opinion it is the most important part of the present book, although it only constitutes about one hundred out of three times as many pages. Its very brevity, indeed, is strongly in its favour, both because it is in contrast with the other very extensive reviews that are published and which for the most part are too lengthy to be read with profit, and also because the shortness of the space devoted to it renders necessary a very careful consideration as to what should and what should not be included. The result is that it embodies almost every important advance without giving a tedious précis of every paper good and bad that has been published during the year. Last year we were very much impressed with the surgical review as compiled by Dr. Bloodgood, of Baltimore, and this year we can extend to it almost the same degree of praise, while adding that the summaries of therapeutics and medicine are in our opinion much improved, and are almost of equal merit with the surgical one, except that the compilers have failed to give to them the personal tone that is so important for the preservation of interest in the subjects discussed. The remainder of the volume includes seventeen contributions from authors of several different nationalities. The best of them is that by Dr. Battle on "The Effects of Quiet Renal Calculus," and is a paper well worthy of careful study. The rest of them are of no special interest, and do not call for any comment.

(*a*) "International Clinics." Vol. IV., 15th Series, and Vol. I., 16th Series 1906. Philadelphia and London: J. B. Lippincott and Co.

SCUDDER ON FRACTURES (*a*).

"The Treatment of Fractures," by Dr. Scudder, is another of the admirable books with which Messrs. Saunders and Co. have enriched medical literature of late years, and which are essentially practical in nature. We feel that the publishers deserve peculiar gratitude for the lavish way in which they prepare the books they present to the profession. The volume before us contains 739 illustrations of exquisite workmanship—radiographs, half-tones, and diagrams—which leave one wondering if it is possible for reproductions in the future to attain a higher degree of grace and realism combined. In thus thanking the publishers we by no means intend to detract from the credit due to Dr. Scudder and his associates, for of their work it is impossible to speak too highly. Indeed, it seems to us that the publishers are as happy in their author as the author is in his publishers, which is another way of saying that an organised combination of author, illustrator, and publisher has in this, as in other cases to which we have referred lately, produced work of the highest class. The various fractures are depicted in well selected radiographs, the external appearances of the injured parts are reproduced in no less excellent half-tones, whilst such graphic photographs of each step in the reduction and fixation of each fracture are given that it would seem the easiest matter in the world to diagnose and treat a breakage in any part of the human body. If we take, for instance, the question of injuries about the elbow-joint, we find two beautiful drawings of the bones of the elbow, and photographs of the normal appearance of the joint and of the methods by which the joint may be examined. Next, there are twenty drawings and diagrams of the different fractures of the bones about the joint; three photographs of actual patients suffering from such fractures; twenty-six radiographs of fractures about the joint; and twelve photographs and drawings of methods of reduction and of application of splints. All the other regions are treated with an equal prodigality of illustration. A valuable chapter is written on the employment of plaster-of-Paris, and each step in the process of the preparation and application of plaster to different regions is displayed in photographs of great clearness, no less than thirty-five being reproduced for the purpose. Some notes on dislocations, again illustrated by photographs and radiographs from living subjects add not a little to the completeness of the volume, but the dislocations are not treated with the same fulness and circumstantial detail as the fractures. So prominent a feature do the illustrations of this book constitute that one is apt to assign a secondary place to the text. This, however, is written with care and judgment, and as the outcome of the experience of an American surgeon to a large hospital, it will have a special interest for medical men in this country. The style is brief and business like, and not without an attraction of its own. Tedious detail does not encumber the descriptions, and there are but few records of cases. Those that are included, however, are worthy of their place. A little-known injury, stated not to be very unusual in young adults, is described and illustrated on pages

(*a*) "The Treatment of Fractures." By Charles Lacke Scudder, M.D., Surgeon to the Massachusetts General Hospital. 5th Edition. Thoroughly revised. 739 Illustrations. Philadelphia and London: W. B. Saunders and Co., 1905. 21s. net.

385 and 387. This consists in the starting and projection forward of the upper epiphysis of the tibia, and is said to be often associated with apparently trivial injuries. The radiograph which is reproduced to illustrate the condition leaves no doubt as to its actual occurrence. We are naturally inclined to criticise some of the views expressed by the author—such, for instance, as that massage and passive movements should not be begun till the second week after a Colles' fracture—but we can say without reserve that in the main they are as sound as they are clearly expressed. This book will be found of great use by general practitioners, especially such as have but few cases of fracture occurring in their practice, for in it they will find lucid descriptions and illustrations of every breakage they may be called upon to treat, and of the way to manipulate and apply their splints. To the hospital and colliery surgeon it will be a mine of wealth, and, as in itself a thing of beauty, it will be a joy for ever.

ALLGEMEINE PATHOLOGISCHE-ANATOMISCHE DIAGNOSTIK.(*a*)

A certain knowlege of the naked eye appearances of morbid tissues is nowadays regarded as a part of the necessary equipment of a medical man. It is regrettable that in this country such knowledge, so far as it is required for examination purposes, takes the form of an acquaintance with museum specimens, which have lost many of the characteristic features of the fresh tissues. It would be a great advantage to the student if a part of the patient and careful teaching which he receives from the anatomist were devoted to training him in the systematic observation and description of the appearances of normal fresh tissues.

The book which is the subject of this review is intended to develop a systematic scheme for the examination by sight and touch of the organs and tissue of the body *post mortem*. By the use of such a routine the pathological diagnosis emerges of itself at the close of the examination, which is the only sound method of arriving at it.

The division of the subject naturally falls into a macroscopic and a microscopic portion, of which the former is by far the most important for the English reader. We have in English many good books on microscopic pathology; there is none which contains a description of naked eye appearances so full, clear, and simple as that which is to be found here.

The first section is on the method of investigation, and here we have general rules for the accurate observation of the size, shape, and consistence of organs, the colour degree of moisture or dryness, of smoothness or roughness of surfaces.

Then follows an admirable chapter on the causes of death, which should be studied by everyone who has to make a *post mortem*. The immediate causes of death are divisible into those which concern the heart, the lungs, and the brain. The signs by which each of these may be recognised are clearly and fully brought out. We have then an account of the general methods of macroscopic diagnosis of various pathological conditions, circulatory disturbances, exudations, forms of degeneration and necrosis, ulcers, tumours, etc., and the macroscopic portion of the book ends with a description of the examination of the special organs and tissues, giving very briefly the technique of the *post mortem* examination in each case, and going into some detail on the commoner morbid conditions. All through the system laid down in the earlier chapters is followed out, the variations in the size, consistence, etc., being dealt with for each organ.

The microscopic portion is chiefly valuable to the English reader for the details given as to the appearance of fresh sections. It covers the same ground as O. Israel's book on pathological histology, but the absence of illustrations makes it less interesting to the general reader. Here, again, the general chapters, dealing with the various forms of cells and intercellular substance, are excellent. The book is primarily one for students, but it contains much that will be found useful and interesting by any medical man.

(*a*) "Allgemeine Pathologische-Anatomische Diagnostik." Von Dr. K. Oestreich, Privat dozenten an der Universität Prosektor des Königen Augusta Hospitals zu Berlin. Verlag von S. Karger, Karlsrasse, 18, Berlin.

DEMONSTRATIONS OF ANATOMY. (*a*)

A volume that has reached a twelfth edition, and that has in its previous editions been familiar to successive generations of medical students, needs little recommendation by the press to prove that it is worthy of taking its place among the standard text-books of human anatomy. The name of the present editor, moreover, bears testimony to the character of the present production. Under the circumstances, therefore, we are in a position to freely criticise, and we will begin with the illustrations. Many of these are reproductions of the celebrated "Illustrations of Dissections" which first saw the light more than forty years ago, while in addition many new ones, partly borrowed and partly original, have been introduced. Many, moreover, have been improved and made more striking by the use of colours for the arteries and veins. Despite all this, however, the eye that has become educated to the beautiful drawings that are to be found in many other English, American, and German text books cannot but fail to notice a lack of that artistic appearance with which it has become familiar. The words "rough" and "crude" come readily to the tongue, while looking at them, and one experiences a distinct sense of disappointment at finding such a reproduction of Dixon and Birmingham's beautiful drawing of the pelvic peritoneum, as is to be found on page 377. We do not mean to state that the drawings fail to represent correctly the proper anatomical position of the structures delineated, for most of them are correct enough, but rather that they are not modern enough in their type and that they are far from artistic. For example, the drawing of the muscles of the outlet of the pelvis on page 382 may have been good enough in the days before formalin came into use, but it is certainly far from pleasing, and we know from personal experience in teaching that many students look upon it as an insoluble puzzle. Again, the relations of the abdominal viscera are very inadequately portrayed, and many of the illustrations of the brain, as, for example, that on page 748, are weak. Proper perspective, also, is wanting in many of the pictures, as, for example, in that on page 466. On the whole, we may say that the best of the illustrations are those which have been borrowed direct, and that few of them have been improved by the borrowing.

As regards the text, we have less to say. Most of it is clear and to the point, and the student who follows it while actually dissecting should find himself enabled to do without the aid of a demonstrator. Dr. Addison's method of marking out the viscera on the surface is that made use of, and also his method of subdivision of the abdominal cavity. Unfortunately, however, some examiners refuse to accept his methods, and this may prove a difficulty in the future to candidates who derive all their anatomical knowledge from this book. We are rather disappointed also to find such little reference to peritoneal compartments, as distinct from peritoneal folds, and we notice also the absence of any reference to the fascia propria of the prostate, and to the renal fascia. Numerous other omissions might be mentioned, but enough has been said to call attention to what we regard as the defects of the book. It has the advantages of being cheap, of comprising the outlines of anatomy in a single handy volume, and of having a very complete list of side references in the pages which facilitate the looking up of any required point.

(*a*) "Ellis's Demonstrations of Anatomy." Twelfth Edition. Revised and Edited by Christopher Addison, M.D., F.R.C.S. Illustrated by 306 wood engravings, of which 75 are in colour. London: Smith, Elder and Co. 1905.

MEDICAL NEWS IN BRIEF.

Doctors in Congress.—British Medical Association at Toronto.

THE annual meeting of the British Medical Association opened at Toronto yesterday, and will continue until Saturday next. Among those who are attending the Congress are the president, Mr. George Cooper Franklin, surgeon, Leicester Infirmary; Sir James Barr, Sir Victor Horsley, Dr. Anderson Griffith, Professor Arthur Robinson (Birmingham), Dr. Norman Walker (Edinburgh), Dr. J. Dundas Grant (London), Sir Thomas Barlow, Dr. Freeland Barbour (Edinburgh), Mr. Marcus Gunn (London), Dr. G. A. Sutherland (London), Professor W. D. Halliburton (London), Dr. Julius Mickle (London), Sir Hector Cameron (Glasgow), and Dr. Donald MacAlister (Cambridge). Two Canadian doctors will act as chairmen of sections—Professor J. G. Adami (Montreal) in the section for patholgy and bacteriology, and Dr. Frederick Montizambert, I.S.O., in that for State medicine. After four days' work, Saturday will be devoted to excursions. The president-elect of the Association is Mr. R. Andrews Reeve, Dean of the Faculty of Medicine, University of Toronto.

The following is the programme arranged for the annual meeting :—

TUESDAY, AUGUST 21ST.—9.30-12.30 a.m., meetings of Sections; 2.30 p.m., address of welcome, introduction of guests, delegates, &c., president's address; 4.30 p.m., in University Quadrangle a reception and garden-party by the president-elect and Mrs. Reeve; 8.30 p.m., address in obstetrics, Dr. W. S. A. Griffith; 9.30 p.m., reception by the Lieutenant-Governor.

WEDNESDAY, AUGUST 22ND.—8 a.m., National Temperance League breakfast; 9.30-12.30 a.m., meetings of Sections; 2.30 p.m., address in medicine, Sir James Barr, M.D.; 4.30 p.m., garden parties; 8.30 p.m., address in surgery, Sir Victor Horsley, F.R.S.; 9.30 p.m., reception.

THURSDAY, AUGUST 23RD.—9.30-12.30 a.m., sectional meetings; 4.30 p.m., garden parties; 7.30 p.m annual dinner.

FRIDAY, AUGUST 24TH.—9.30-12.30 a.m., sectional meetings; 2.30 p.m., general meetings; 4.30 p.m., garden parties; excursions; 8.30 p.m. soirée.

SATURDAY, AUGUST 25TH.—Excursions to the Niagara Power Company's plant, through the courtesy of Sir Henry M. Pellatt; excursion to Muskoka; excursion to Lambton, through the courtesy of the president, Mr. Austin.

Irish Midwifery Qualifications.

IN the House of Commons, Mr. Healy recently asked the Prime Minister whether he was aware that although Dublin contained the largest and oldest chartered school of midwifery in the Empire, and the second largest in the world, the profession of midwife in Ireland, which had been organised for more than 150 years, had been gravely prejudiced by the action of a newly-constituted body in England (which was not yet four years old), in refusing to recognise the Irish midwifery qualification and inducing Government departments to stipulate in advertisements that the new English qualification would alone be recognised; was he aware that the Irish midwifery schools, which now attracted students not only from Great Britain and the Colonies but from the Continent and the United States, had without effect protested against the slur officially cast on the older Irish qualification; would he inquire whether the English Central Midwives Board refused to hold any examination in Ireland (although guaranteed the expense), so as to handicap Irish midwives and put them to the outlay of a ten days' visit to England; and, if so, would the Government allow the Midwives Act, 1902, which was passed with the consent of all parties, to remain in force.—Sir Henry Campbell-Bannerman replied that the Central Midwives Board had not refused to recognise the Irish midwifery qualifications, nor had it induced, or endeavoured to induce, Government departments to stipulate in advertisements that the qualification of its own certificate would alone be recognised. As to the refusal of the Board to hold examinations in Ireland, of which the honourable member complained, he was advised that by the terms of the statute such examinations could not be held in Ireland.

Post-Office Medical Officers at Glasgow.

THE Postmaster-General has made his selection out of the 300 odd applications he had received in reply to the advertisement for six medical officers for Glasgow Post-Office. Following upon the death of Dr. Dougan, who as medical officer to the Glasgow Post-Office devoted his whole time to the duties, it was deemed inadvisable to continue the system of appointing only one medical officer, owing to the growth of the department, and the wide area in which the men reside. The postal area has been arranged into six districts, and a medical officer attached to each. The gentlemen appointed are at liberty to engage in private practice. The following medical practitioners have been appointed :—Central District—D. Watson, M.B., 116, Mains Street. Western District—R. O. Adamson, M.D., 15, Grosvenor Crescent. Southern District—W. Lawson, M.D., 36, Glencairn Drive, Pollokshields. Eastern District—J. Patrick, M.B., 23 Westercraigs. Northern District—J. M'Kie, M.B., 24, Hillside Terrace, Springburn. Govan—R. Y. Anderson, M.B., Redcliffe, Bellahouston.

Retirement of Mr. Herbert Page.

AFTER thirty years of surgical work at St. Mary's Hospital, Mr. Herbert Page has ceased to be a member of the active staff, and has been appointed Consulting Surgeon. Mr. Page was elected surgeon for out-patients on February 16th, 1876, and he held this office ten years. From May, 1886, to May, 1906, he had been surgeon for in-patients. From 1876 to 1881 he was lecturer on operative surgery in the Medical School. In 1882 he was appointed a colleague of Mr. Norton in the lectureship on Systematic Surgery. On Mr. Norton's resignation in 1888, Mr. Page was associated with Mr. Owen, and in 1897 with Mr. Pepper, in this duty. In 1900, after eighteen years as lecturer in surgery, he was appointed lecturer in clinical surgery. For two years (1888-1890) Mr. Page was Dean of the Medical School, and from 1892 to 1906 has been its Honorary Librarian. Some excellent samples of his teaching have been preserved for us in the small volume of Clinical Lectures which Mr. Page published in 1897, dedicated "To my past House-Surgeons," and entitled "Clinical Papers on Surgical Subjects." Mr. Page's long experience as Surgeon to the London and North-Western and the Great Western Railways has made him an acknowledged authority on the subject of the symptoms directly or indirectly produced by injuries caused by railway collisions, and he was much in request as a witness in "railway cases." It may be mentioned that at the expiration of his term of office, Mr. Page's generous interest in the future welfare of the Hospital has manifested itself in a donation of a hundred guineas, which is, by his request, to be devoted to the cost of the equipment of the new operating theatre for general surgery in the Clarence Wing.

Death from Hæmophilia.

An inquest was held by Mr. Coroner Hoyle at the Newcastle Infirmary, on August 6th, touching the death of John Wilson, aged three years, who died in the institution. Bertha Wilson, of 38, Franklin Street, Shieldfield, identified the body as that of her son, who, she said, had been quite healthy from birth. On Monday, July 9th, the child was playing in the yard when he fell down, and knocked his head against the wall. There was a lump on his head, which did not go away, but the child never complained of any pain from it. On the following Wednesday, the child came into the house, and complained that a child, about the same age as deceased, had kicked him on the knee. On the same afternoon witness took the boy to the Infirmary, where his leg was attended to. The doctor also noticed the lump on the boy's head, and lanced and dressed it. The boy was all right after that, until midnight on the following day, when the place on the head commenced to bleed, and continued bleeding. At 6.45 a.m. on the Saturday, witness took the boy to the Infirmary again, and the cut made by the lancing was dressed. Witness was told to go back if the blood showed through the bandage, and as it did so witness took the boy back again at 2.45 in the afternoon. The doctor she saw on that occasion, however, refused to examine the deceased's head, as it had already been once dressed that day. As, however, the bleeding continued, she tried to stop it with cold water, Dutch-drops, and spider's webs, but failed. She took the boy to the Infirmary on the Sunday night, when the head was dressed, and the bleeding stopped. A few days afterwards an abscess formed, and on Wednesday last the boy was detained at the Infirmary. Witness was informed that the abscess burst on Friday night, and the child died on Saturday night.

Dr. Willon, house-surgeon, deposed to having examined the child. Witness did not know of the injury to the leg, and apart from the abscess on the head, the child was suffering from a constitutional disease, and was what is commonly known as a "bleeder." That was the reason why the bandage had not been taken off; for if the pressure had been removed the child might at once have bled to death. It was common knowledge among the doctors that the child was a "bleeder," and that was the reason the doctor referred to by the last witness had refused to touch his head. After the first abscess burst, a second formed, and that had to be opened. The child, being predisposed to the constitutional disease, subsequently died from exhaustion, as the result of the bleeding.

TheCoroner said he had no doubt that the jury would be quite satisfied with the doctor's explanation. If the bandages had been taken off in their congealed state the probability was that the child would have bled to death there and then. The jury concurred with the Coroner, and found that death was due to exhaustion, consequent upon an abscess, which was caused by an accidental fall.

Professor Behring and Tuberculosis.

Prof. von Behring read a paper on Tuesday on the results of the researches he is making with the object of discovering a remedy against tuberculosis. He announced that he had succeeded in obtaining from tubercle bacilli a preparation to which the name of tulase has been given, and which differs essentially from Koch's tuberculin. With the help of this preparation he had been able to render animals immune against infection from the virulent tubercular bacilli. He stated that it was not impossible that preventative and healing effects might subsequently be attained by means of tulase. Clinical experiments which had hitherto been made with this substance, and which had proved that it exerted a very favourable effect on scrofulous and tuberculous diseases of children, had consisted exclusively of sub-cutaneous injections.

Queen's College, Cork.—The President's Report.

The annual report of the President of the Queen's College in Cork travels somewhat beyond its usual scope, and deals at length with the causes that tend to interfere with the full development of the Arts classes. According to the President, while extreme pressure has been brought upon students not to attend the Arts classes, the objections raised to attendance upon courses of medicine and engineering have not been nearly so great. He adds that it is quite hopeless to look for any improvement in the entries for Arts courses until some radical change has been made in the conditions of the College. Dr. Windle then quotes from his own experience of the Queen's College and the Mason College in Birmingham, and points out how reconstruction and amalgamation of the two have resulted in the great and progressive University of Birmingham. In conclusion, he urges that some effort should be made to place the College on a better footing.

Birth-rate in England.

England's birth-rate for the second quarter of the present year is the lowest recorded for any parallel period since civil registration was established. According to the Registrar-General's returns issued on August 14th, the natural increase in population in England and Wales during the quarter, by excess of births over deaths, was 111,800, against 117,850, 114,389, and 113,726 in the second quarters of 1903, 1904, and 1905 respectively. The births registered during the three months past are in the proportion of 27·5 annually per thousand of the population. The mean rate in the ten preceding second quarters was 29·1. In the registration, counties with a population exceeding 100,000 persons the lowest birth-rates during the quarter were: 21·3 in Sussex, 21·5 in Cornwall, 21·7 in Hertfordshire, 22·5 in Somersetshire, and 22·7 in Devonshire. The highest rates were 31·1 in Northumberland, 31·6 in Staffs, 32·1 in the North Riding of Yorks, 33·8 in Glamorganshire, 34·8 in Durham, and 35·5 in Monmouthshire.

Deaths registered in England and Wales last quarter numbered 125,387, and were in the proportion of 14·6 annually per 1,000. This compares with an average rate of 15·9 in the parallel periods of the ten preceding years. Of the total number, 64,903 were males and 60,484 females. Babies who died ere they attained a year numbered 24,311, the rate being 102 per 1,000, as compared with an average of 119 in the ten preceding second quarters. In the large towns the infantile mortality averaged 108 per 1,000 of the births. Burnley's rate was the highest—165.

Poisoning in British Guiana.

From Georgetown, British Guiana, comes news of an attempt to poison Professor J. B. Harrison, Director of Science and Agriculture and Government Analyst, and the whole of the laboratory staff. In June, Professor Harrison was incapacitated by a mysterious illness, which recurred in spite of skilled treatment. About the same time the laboratory was more than once entered by some unknown person at night. The burglars were apparently possessed of duplicate keys. On July 5th, Professor Harrison, after drinking ice-water from the can, was seized with headache, giddiness, and nausea. Meanwhile the assistants at the laboratory, Messrs. P. V. Garraway, Christiani, and Matthews, and the messenger, developed similar alarming symptoms after drinking ice-water from the reservoir. On the Monday it occurred to Mr. Garraway that their illness might be due to poison, and an inspection of the water receptacles showed that enough "Rough on Rats" had been placed therein to poison hundreds of people. Fortunately, all the victims have nearly recovered by now. No clue to the perpetrator of the outrage has been found.

Cancer in Essex.

Dr. Thresher, the Medical Officer for Essex, in summarising the reports of the various local medical officers in the county, states that year by year the death-roll from cancer is increasing, the figure of 527 in 1900 being increased to 721 last year. At present it causes about the same number of deaths as all the following diseases put together:—Small-pox, scarlet fever, measles, diphtheria, typhoid fever, and whooping cough.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Inguinal Hernia.—In discussing inguinal hernia, White (*New York Med. Journ.*, July 14th, 1906) points out that two muscles, or the two edges of muscular tissue which lie parallel, brought close together by suture, will not unite unless the edges are freshened. In a successful case of Bassini's operation, if a dissection were made exposing the external edge of the internal oblique and the inner edge of Poupart's ligament, they would most probably be found simply lying together in a transplanted position without firm union. The author realizes the difficulty of freshening the edges of Poupart's ligament, and the internal oblique. Catgut sutures may train these parts to lie close together, yet if there is no union there will be a weak spot in that part of the abdominal wall, which may account for some of the failures in Bassini's operation. The author cuts out a V-shaped piece of tissue in the external oblique, leaving a freshened surface which will unite, and form a tense muscular wall over the weak place in the abdominal parietes. S.

Hernia of the Bladder.—Kivlin (*New York Med. Journ.*, July 14th, 1906) discusses this subject and describes three cases. Case I.—Patient showed an enlargement of the hernial site in the left inguinal region. There was a fluctuating swelling, dull on percussion, pressure on which gave rise to an instant desire to urinate. The swelling disappeared after micturition. Internal ring was enlarged. Case II.—Patient felt a sharp pain in left inguinal region four years ago, while lifting a weight. Since then he wore a truss. At the operation a sac was found which had no neck. Some adherent omentum was freed, ligatured, and cut off. To the inner and lower portions of the sac was very firmly adherent what appeared to be bowel, but on closer examination proved to be bladder. This could be traced behind the pubis. There was an unusual amount of fat in the inguinal canal, and this is said to be diagnostic of the condition. Some of the sac was cut away and closed with interrupted suture. The muscle was closed by interrupted sutures and the aponeurosis with continuous catgut. No return of the hernia occurred. Case III.—Patient, æt. 64, had suffered from hydrocœle for fourteen years. One week before operation, while moving a large stove, patient felt a sharp pain in the left inguinal region. During examination, pressing the finger well down into the abdomen gave the patient a desire to urinate, which he promptly did, passing more urine than he had done at any previous time since the trouble began. He felt fairly well relieved of his trouble. At the operation an excessive amount of fat was found in the canal. The sac was opened, and the bowel which was adherent to it was liberated. There was no neck to the hernial sac, but to the inner side of it was the protruding bladder which was extra-peritoneal and entirely independent of the sac. The bladder protruded and was free for about an inch from the margin of the transversalis muscle of the left side. The sac, which could not be tied off, was closed with continuous catgut, after ligaturing the cord and removal of the testicle and cord. The hernia of the bladder was pushed back and the direct opening closed. The abdominal layers were sutured together. Patient was discharged cured in fourteen days. S.

A New Incision for Removal of the Breast.—In making his incision, Carl Beck (*Medical Record*, July 14th, 1906) utilises the fact that below the mamma there is an abundance of integumental material. He begins by giving his incision line round the breast the form of a rectangle. The interior line of the rectangle is continued on both ends to the extent of about three inches. The same is done with the lower end of the external side, while the upper exterior end is extended along the margin of the pectoralis major muscle up to its humeral insertion. The axilla itself is not touched, in order to avoid cicatrization which is apt to produce œdema brachii. After the rectangle, including the whole breast, is excised, the upper skin flap is formed and reflected. The author is in favour of the most radical procedure as advocated by Halsted. The pectoralis major and minor are removed, and the axillary contents dissected away, so that the vessels are completely isolated. The lower flap is next lifted up and reflected. If there is any tension, the lower flap is made longer by extending the incision lines on both sides. The straight shape of the flaps greatly facilitates exact coaptation. There is no tendency for the flaps to separate, with the formation of irregular cicatrization, which so often happens with the oval or elliptical incision. S.

The Exposure of the Heart for Heart Wounds.—Wilms (*Centrblt. f. Chirurgie*, July 28th, 1906) considers that the flap operation is only suitable for wounds in the anterior wall of the heart. There is great difficulty in reaching the back of the heart by the above incision. The author describes a recent experience in the case of a bullet wound. A bullet of 6 mm. calibre entered about the middle of the left ventricle anteriorly, and emerged in a corresponding situation behind. In this case, if a flap operation had been employed, the posterior aspect of the heart could only have been sutured after resection of the sternum. The author, therefore, employed a long intercostal incision. This is best situated in the fourth or fifth intercostal space. If it is considered desirable to enlarge the opening, the fourth and fifth ribs can be removed near the sternum. When the pericardium is opened a very good view of both the front and back of the heart is obtained. The operation can also be more quickly performed. The pneumothorax which supervenes is no further complication, and it is impossible to avoid it in any flap operation. In the above case, two hours after the accident, the entrance and exit wound in the heart were each closed by three sutures. The wounds in the lung, pericardium, and thoracic wall were also completely closed without drainage. Hæmorrhage was considerable, and amounted to about a litre and a quarter. The wound healed quickly by first intention. The author considers that the intercostal incision will supplant the flap operation in injuries to the heart. It considerably shortens the duration of operation, and gives a better view and access to the heart than an equally extensive rib section. S.

A New Form of Intestinal Obstruction: The Methods for Preventing a Recurrence of Volvulus of the Sigmoid Flexure.—Moschcowitz (*New York Medical Journal*, July 14th, 1906) discusses the operative treatment of volvulus of the sigmoid flexure, especially in reference to the prevention of its recurrence. Sigmoidopexy, that is, the anchoring of the sigmoid flexure to the anterior abdominal wall, by a row of catgut or silk sutures, is the method usually employed by the author. Obalinski's method of resection of the entire sigmoid flexure, with end to end anastomosis, is severe but necessary in gangrenous cases. Senn's method of reefing the meso-sigmoid endangers the blood-supply of the gut, and is often impossible to perform on account

of the thickening of the mesentery in volvulus. Roux's method of anchoring the sigmoid flexure to the anterior and lateral abdominal wall, by sutures passing through its mesentery, is a modification of sigmoidopexy but more difficult to perform with the pathological meso-sigmoid. Riedel's method of dissecting out and removing all the cicatricial bands and deposits which are usually found in the meso-sigmoideum in cases of volvulus, is a difficult and lengthy operation, and worse adhesions are liable to form. Phillippowitz's method of anastomosing the cæcum with the efferent limb of the sigmoid flexure, depends for its success on the fixation of the sigmoid flexure, and the anastomosis is unnecessary. The author describes a case to illustrate the difficulty of preventing the recurrence of symptoms, and the further strangulation of intestines. S. S., a male, æt. 41, was admitted to hospital with symptoms of complete obstruction lasting four days. Patient had hiccough, vomiting, and absolute constipation, the abdomen was enormously distended. A median incision six inches long was made in the abdominal wall. The volvulus consisted of three feet of sigmoid flexure, the gut being at least six inches in diameter. This bowel was emptied by a rectal tube. It was then stitched to the left half of the anterior abdominal wall for about two and a half inches by a number of interrupted silk sutures. The patient made a satisfactory recovery. Three weeks after the operation symptoms of obstruction again appeared, necessitating a second laparotomy. The small intestine was found greatly distended. When the distended coils were traced to the outer (left) side of the sutured sigmoid, they were found incarcerated in a pocket between it and the lateral abdominal wall. The sigmoid was therefore freed, the adhesions removed, and the intestines liberated. The patient rallied somewhat after the operation, but died two hours afterwards. S.

Joint Diseases, especially those of Children.—In a paper on this subject, F. Willard (*New York Medical Journal*, June 23rd) calls attention to the great frequency with which mistakes occur in the diagnosis of painful joints. He discusses the signs and symptoms of the commoner varieties of joint disease, and draws particular attention to the following points:—(1) Early diagnosis is the most important of all considerations. Physicians are responsible for a large majority of joint destructions, chiefly from carelessness or indifference in the examination of their patients. A child with any peculiarity of gait should be examined naked. (2) Every physician should abandon the thought that pain in a single joint in a child means rheumatism; a limp, with rigidity of the peri-articular muscles always means some form of invasion, possibly septic, probably tuberculous. (3) Abort tuberculous infection by immediate aboslute rest, and fixation of the joint. (4) Put the patient out of doors, day and night, for a long period of time. (5) Wise conservatism consists in the prompt application of all methods of relief. whether hygienic, mechanical or surgical. In children conservatism should be the rule; in adults, operative measures are much more frequently demanded. A limb that can readily be saved in a child, in the adult will demand amputation. If an operation will best accomplish a cure, such operation is true conservatism. (6) In septic cases, open early and freely.

G.

Intestinal Obstruction due to Reflex Nerve Disturbance.— Dr. C. Clubbe (*Intercolonial Med. Jour.*, May 20th) draws attention to this condition, giving the histories of several cases, in which the intestinal obstruction was due to a reflex nerve disturbance the lesion being outside the peritoneum, and the obstruction at once relieved when the irritation subsided. The author then goes on to discuss freely the various theories as to the cause of this nervous obstruction He believes that if we have reason to suspect, in any given case, that the intestinal paresis is due to a reflex nerve irritation, then, if we can find a cause, which we think is sufficient to set up reflex inhibition, all we have to do is to relieve tension by letting out pus, whether it is in the abdominal wall, or behind the peritoneum in the region of the kidney, or wherever it may be. If the inflammatory trouble has been causing nerve irritation, and so, reflexly, intestinal obstruction nothing more need be done at the time. The abdomen need not be opened, for the intestines will take care of themselves. The importance of this fact will appeal to all those who come in contact with this class of case, for what can be more disconcerting to the surgeon, or inauspicious for the patient, than a futile search from duodenum to sigmoid for an obstruction that does not exist? G.

On Convergence in Corrected Myopia.—Bourdeaux (*Soc. Franc. d'Ophthal.*, Mai, 1905) explains the vertigo, diplopia and headache so often heard of after full correction has been ordered to myopes as being due to the altered relations between convergence and accommodation. Before correction a myope has to exercise more or less convergence when looking at something at his far point. When he adopts glasses there is still a tendency for the convergence to be in excess of the accommodation, so that if he has binocular vision it is not acquired with ease until the new relations are established. M.

Early Detachment of the Retina in Sarcoma of the Chorioid.—J. H. Parsons (*Ophthalmic Review*, June, 1905) has made an anatomical examination of fifty cases of sarcoma of the chorioid and ciliary body, and gives the following conclusions:—Detachment of the retina occurs earlier in sarcoma than is generally gathered from our text-books. The growth, of course, lifts up the retina, but there is no true detachment over it. The true detachment occurs invariably as a shallow detachment in the lower hemisphere, having no connection with the portion of retina covering the young tumour. If there is a connection between the two detachments it is simply due to the accidental position of the tumour in the lower hemisphere. When the tumour commences above there is always an area of normally-placed retina between the tumour and the true detachment below. Total detachment usually supervenes. M.

Tubercle of the Chorioid.—G. Carpenter and S. Stephenson (*The Ophthalmoscope*, August, 1905) give a full description of such a case, which revealed some unusual features. According to the authors, tubercle of the chorioid is by no means uncommon, and forms a very trustworthy sign of acute miliary tuberculosis; out of forty-two case of acute miliary tuberculosis and tuberculous meningitis which they examined ophthalmoscopically, 50 per cent. had chorioidal tubercle In the case recorded, where there was progressive wasting, oscillating temperature, rapid pulse cyanosis, hurried respirations without adequate physical cause the diagnosis was finally settled by the detection of the tubercles in the chorioid. The unusual features of the case consisted of the presence of the tubercles in both eyes and in large numbers. Instead of there being just two or three fawn-coloured spots there were about twelve situated in the "central region" of the fundus of each eye. A second point of interest in the case was the presence of outstanding nodules of tuberculosis of the retina, which seemed quite unconnected with the chorioidal nodules. The discovery of the bacillus tuberculous in these retinal deposits set at rest some doubt the authors had as to their eal nature. M.

Note.—*A Summary will appear each week in the following sequence:*—(1) "*Recent Medical Literature.*" (2) "*Recent Surgical Literature.*" (3) "*Recent Gynæcological and Obstetrical Literature.*" (4) "*The Recent Literature of Physiology and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

M.D. (Llantrissant).—Prof. A. Bergt, acting director of the Ethnological Museum at Leipzig, is one of the best men to answer the questions you suggest.

GLASGOW STUDENT.—1. Prof. Wyndham Dunstan has written a paper on the new radio-active mineral thorianite from Ceylon. It will be found among the reports of the Royal Society. 2. The annual meeting of the American Röntgen Ray Society is, this year (Aug. 29), at Niagara Falls.

DR. G. (Brondesbury).—You can get all the information you require with regard to hotels and inns for week-end motoring trips in the "Holiday Number" time tables of the chief railways. They also give the names of houses where "week-enders" are taken.

RADIUM.—With regard to acute erythema resulting from Röntgen Ray treatment the stearate of zinc composition powder, with 10 per cent. ichthyol, seems to act as a prophylactic and prevent serious burns.

SANITAS.—1. There are endless manuals on the subject, but the largest and most comprehensive is the "Practical Guide to Public Health Acts," by T. W. Hime (Baillière, Tindall and Cox), price 15s. 2. The usual plan is to saponify the butter with alcoholic potassium hydrate and then test for boric acid in the ash as usual.

FANGO DI BATTAGLIA.

SIR,—In your issue dated August 15th I notice under the heading of "British Health Resorts" an article on Matlock Bath and more particularly on the Royal Hotel there. Your correspondent has been wrongly informed when he says that the treatment by Fango di Battaglia can at present be obtained only at Matlock Bath in this country. The same treatment is in use at Smedley's Hydro., Matlock, and has been in use there during the last three years. It is only fair to the neighbouring institution that this mis-statement should be corrected in your next issue. I am, yours truly,

GEORGE C. R. HARBINSON, M.B., B.Ch.

Smedley's Hydropathic Establishment,
Matlock.

[We have received a letter from another correspondent to the same effect. "Fango" is merely Italian for "mud," and mud-baths of one kind and another are in use at many spas in Great Britain. "Fango di Battaglia" is an extremely fine deposit of volcanic origin thrown up by the hot springs at Battaglia in Italy. It is this particular "mud" which is used at Homburg, Baden-Baden, Marienbad, and Kissingen, and is now imported for use at Matlock Bath, and our correspondent believed solely imported by them for use in this country.—ED.]

DR. H. (St. Neots).—There is no doubt about the increased frequency of chorea among Board School children, and school work, if persisted in during the early stages, both retards recovery and intensifies mental distress. Many children may appear to be cured, but a return to school work causes a recurrence of the irregular movements.

TRAVELLER.—We quite appreciate your difficulties about ascertaining the sanitary condition of a place before sending a patient. The sewage saturation of the subsoil both in Port Said and Cairo is rapidly becoming a menace to public health, but the Department of Public Health is engaged in finding a remedy. Why not try Hamman R'hira in Algeria. The environment is almost as beneficial as the baths.

THE latest patent "cure" for distemper is registered by T. A. Palfrey, of Stirling Street, Alva, Clackmannanshire. It is composed of phenacetin, ammonium chloride, gentian root, and armenian bole. The mixture is used as a capsule filling.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 22nd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X Rays. Operations. 5 p.m.: Lecture: Practical Demonstration in Cystoscopy.

THURSDAY, AUGUST 23rd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Eye.

FRIDAY, AUGUST 24th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—2 p.m.: Diseases of the Throat, Nose, and Ear. Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations. Diseases of the Skin.

SATURDAY, AUGUST 25th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—10 a.m.: Diseases of the Throat, Nose, and Ear. 2 p.m. Medical and Surgical Clinics. 2.30 p.m.: X-Rays. Operations.

Vacancies.

Royal Hamadryad Seamen's Hospital. — Medical Superintendent. Salary £250 per annum, together with furnished residence, firing, lights. Applications to Ivor J. Roberts, Secretary, 4, Docks Chambers, Cardiff.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

City and County of Kingston-upon-Hull.—Appointment of Resident Medical Officer, Infectious Diseases Hospitals. Salary £200 per annum, with residence, board, and washing. Applications to E. Laverack, Town Clerk, Town Hall, Hull.

Chesterfield and North Derbyshire Hospital and Dispensary.—Senior House Surgeon. Salary £120 per annum, with board, apartments and laundress. Applications to the Secretary at the Hospital.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Luncheon is provided at the Hospital. Applications to W. M. Wilcox, Secretary.

Fisherton Asylum, Salisbury. — Second Assistant Medical Officer. Salary £120 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

York County Hospital.—House Physician. Salary £100 per annum, with board, residence, and washing. Applications to Fredk. Neden, Secretary and Manager.

The Middlesex Hospital, W.—Second Assistant to the Director of the Bacteriological and Clinical Laboratories. Salary £100 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

County Asylum, Dorchester. — Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Royal Victoria Hospital, Dover. — House Surgeon. Salary £100 a year, with board, lodging, and washing. Applications to the Hon. Secretary, Arthur B. Elwin, Esq., 2 Castle Street, Dover.

York Dispensary.—Resident Medical Officer. Salary £120 a year, with board, lodging, and attendance. Applications to W. Draper Esq., De Grey House, York.

Appointments.

HARRISON, JAMES MCKEAN, M.B., B.Ch., B.A.O., R.U.I., Medical Officer to the Workhouse by the Ledbury (Hertfordshire) Board of Guardians.

HOLLAND, EARDLEY L., M.B., B.S.Lond., F.R.C.S.Eng., Assistant Resident Medical Officer to Queen Charlotte's Lying-in Hospital, London.

LYSTER, ROBERT ARTHUR, M.B., Ch.B., B.Sc.Lond., D.P.H., B.Sc., Medical Officer of Health to the Urban District of Handsworth (Staffs.).

MORRISON, J. W. H., M.B., B.S.Durh., Certifying Surgeon under the Factory and Workshop Act for Blaydon-on-Tyne District of the county of Durham.

SELLS, H. LANCELOT, M.B., Ch.B.Edin., House Surgeon to the Hartlepools Hospital, Hartlepool.

Births.

CHURCHILL.—On Aug. 17th, at Kien-ning, Fuh-Kien, South China, the wife of H. Melville Churchill, M.R.C.S., L.R.C.P., of a son.

JACOB.—On Aug. 14th, at 26 Hindes Road, Harrow, the wife of Archibald H. Jacob, L.R.C.P. and C.S. Ireland, of a daughter.

SELIGMANN.—On Aug. 14th, at 15 York Terrace, Regent's Park, the wife of Charles G. Seligmann, M.B., of a daughter.

SHATTOCK.—On Aug. 17th, at Saville House, Sutton Court Road, Chiswick, the wife of Chas. R. Shattock, M.R.C.S., L.R.C.P., L.D.S.Eng., of a son.

Marriages.

MEREDITH—SMYTHE.—On Aug. 15th, at All Saints' Church, Maidstone, Herbert Duncan Craig, younger son of John E. Meredith, B.A., M.D., of Maidstone to Evelyn, youngest daughter of the late Algernon Sydney Smythe, of Ivythorne, Maidstone.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, AUGUST 29, 1906. No. 9.

NOTES AND COMMENTS.

M.B.M.A.

IN the current issue of "First Aid" (published on the 20th of the present month) the Editor harks back nine weeks to quote the leaderettes on the M.B.M.A. question, which appeared in our columns for June 27th last, and *inter alia* remarks "We think, in common fairness to the association (St. John's Ambulance) and its loyal adherents, they should explain more fully their reasons for this charge; in other words, should give the names of the delinquents." We have pleasure in conforming to the request of our contemporary, and give the name of Mr. Vaughan Bateson, a registered medical practitioner, who affixed to his name on a pamphlet entitled "Notes on First Aid" the letters "M.B.M.A.," in addition to over a score of others, including his medical titles. The editor of the screed mentioned shows in our opinion needless bias in his remarks, and we beg to point out to him that the matter has been already fully dealt with not only by the local (Bradford) Ethical Society, but, what is more important, by the Central Ethical Committee of the B.M.A., who have considered the matter of such importance that they have specially inquired into the question and have issued a decision that these letters "M.B.M.A.," may not be used in the way they were by any member of the British Medical Association.

An Election Scene.

A remarkable scene took place at a meeting of the Cork Guardians the other day, when the question of the election of a specialist to attend for the eye, ear, and throat cases under their jurisdiction came up. It seems that it has been the practice of the Guardians to send patients requiring special attendance for ophthalmic and throat diseases to hospital, and that it was recently considered that it would be a more convenient and economical arrangement to have a specialist engaged to attend cases when necessary. As the specialist was only offered fifty guineas for the first year and sixty guineas per annum afterwards, the proposal can hardly be considered extravagant, but when the business of election to the post came before the Guardians it was found that two well-qualified gentlemen, Dr. D. P. Fitzgerald and Dr. James M. Browne were willing to undertake the necessary duties. The meeting was sharply divided into partisans of the two doctors, one side contending that they wanted a specialist, and the other that a well-educated, well-qualified man should not be left out of the running because he practised generally as well. The partisans eagerly backed up their contentions, and a very hot time ensued, all sorts of improper influences being alleged, and a considerable amount of personal abuse indulged in. An amendment was proposed to adjourn the election for six months, and this took so long to discuss that the Guardians eventually clustered round the rostrum on which the chairman was seated, and banged on it with their hands. In the end this undignified scene came to a close by the amendment being carried; we shall be interested to notice its final result.

School Touting.

WE notice in *Truth* that a doctor recently called the attention of its editor to the methods of the Ebor Educational Agency, of 10, St. Oswald's Terrace, York. This concern sent to the doctor in question a circular asking him on his daily rounds to ascertain in the ordinary course of conversation, without letting parents think that he is interested in the matter, whether they are likely to be sending their sons or daughters to school, and if so to send their names to the Agency with any particulars he could give. For every pupil placed through the doctor's instrumentality a guinea was offered, and he was assured that the Agency had many doctors in different parts of the country now acting for them. We are glad to hear that the doctor declined to have anything to do with such undignified touting, and if the Agency meant that they have a number of doctors who use their profession as a cloak for pushing the Ebor Educational Agency by the underhand methods suggested, for our own part we flatly decline to believe the statement. The Agency, if it descends to such unworthy dodges in working up business, might at least do so on its own responsibility, without seeking to involve in its degradation the members of an upright profession.

Bravo, Mr. Mead!

THERE are always a number of self-opinionated, hot-headed, irresponsible people who are inclined to attribute the worst of motives to others, and of such are the majority of anti-vaccinationists. A man has a perfect right to believe or not believe in vaccination; in a free country a man is allowed to be a fool without let or hindrance, and any man who denies the protective influence of vaccination is as much of a fool as a man who denies the pro-

tective influence of a pure water supply. A wise man may doubt whether universal compulsory vaccination is the best way of stamping out small-pox in a democratic community, and he, too, has a right to his opinion. But it is particularly obnoxious and quite uncalled for that anti-vaccinationists should perpetually be sneering at medical men, and attributing dishonesty to them. We are delighted to see that one of these gentry got a sharp rap over the knuckles the other day. He was applying to Mr. Mead for an exemption certificate, and said that two of his children "broke out in sores" a month after being vaccinated. On being asked what the doctor thought was the cause of the sores, the applicant replied, "Oh, it isn't his duty to say they were due to vaccination." Mr. Mead asked him promptly whether he meant to suggest that doctors were liars, and asked him to apply the argument to his own calling, that of an insurance agent. As the man had not made proper inquiries about the cause of the children's illness Mr. Mead said he could not regard the objection as conscientious, and therefore he declined to grant a certificate.

LEADING ARTICLES.

OPERATIONS ON THE CENTRAL NERVOUS SYSTEM.

SIR VICTOR HORSLEY naturally chose as his subject for the address in surgery at the British Medical Association meeting that branch of the art in which he has had most experience—namely, operations on the central nervous system. He began his address by recalling the facts that it is just twenty years since he showed to the Association the first three patients on whom he had operated for intracranial disease, and that on that occasion the principles he suggested as a guide in cerebral surgery were based chiefly on operations performed on the lower animals. Since 1886 surgeons have been operating on the nervous system in all parts of the world, and the present is, therefore, not an inopportune moment to try to gather from their collective experience the materials for forming a judgment on the utility and range of this department of surgery. Such operations fall, as Sir Victor Horsley pointed out, into two classes, those which are merely palliative and those which are designed actually to cure. The former are directed to relieve pressure symptoms and all the pain and misery resulting from them, and with that object not only are they justifiable but they constitute a positive obligation on practitioners in charge of cases of cerebral tumour. Optic neuritis and its resultant blindness are, unless the optic tract is specifically implicated, due to pressure and pressure alone, and by early operation they may be obviated with certainty, and the terrible headaches, the vomiting, and the other symptoms that make unbearable the life of patients with intracranial growth are equally amenable to the same measure. If cerebral surgery had nothing to point to beyond the ascertainment of these facts, it would not have been attempted in vain, and it behoves physicians never to let the possibilities of these palliative measures slip their memory, nor to wait too long before desisting from drug treatment and handing their patients over to the surgeon. When, however, surgery aims at cure or permanent relief, it is apparent that a number of questions arise, which may well tax the science of neurological diagnosis beyond its present capacity. The nature, the extent, and situation of the growth must all be known or conveniently guessed at, and the practicability of the success of an operation carefully gauged, whilst, moreover, the damage to cerebral tissue which will be inevitable, must be set against present and probable damage by disease. Sir Victor Horsley, we are glad to see, is not moved to join the "forward" school of cerebral surgeons, but entered a wise caution against unnecessary mutilation of the brain. The bulk of the address was taken up in the discussion of the details of operative procedure, beginning with the previous preparation of the patient and ending with the special treatment of individual regions of the brain, and as the outcome of the lecturer's peculiarly long and varied experience, the views expressed have a high value. Surgeons will be particularly interested to learn that Sir Victor Horsley believes that the manner in which the skull is opened is responsible to a great extent for the amount of shock produced, and that he is opposed to using vertical pressure or force; in fact, his own practice is to remove a piece of bone with the trephine, mark out the rest of the area to be removed with saw-cuts, and then cut away that area with bone-forceps by directing all traction outwards. Another practical point which may not be generally known is the ease with which Sir Victor has found capillary oozing to cease when inhalations of oxygen are given to the patient. The oozing is only troublesome when some degree of asphyxia is present, and if congestion be relieved by free stimulation with oxygen, no further measures are needed to control the bleeding. The address will be found full of interest to practitioners of all branches of the profession, for it deals with a department of surgery in which, though its results have not been as brilliant as those in other domains has yet made solid advances which at times are in danger of being overlooked.

THE CIRCULATION FROM THE PERIPHERY.

IN various ways the subject chosen by Sir James Barr for the Address in Medicine at Toronto is one of special interest to the philosophical student of medicine. The author brought to his task not only the ripe experience of a physician, but also a wide range of experimental knowledge. The importance of the capillary circulation in many diseased conditions is becoming more and more recognised. Raynaud's disease may be taken as a specific instance of local asphyxia. It has always hitherto been ascribed to vasomotor spasm, but Sir James Barr has shown that, like other allied asphyxias, it is in reality due to diminished blood-pressure in the arterioles. Similarly defective vasomotor action leads to congestion of the areas

involved, such, for example, as happens in orthostatic albuminuria, when the cause mentioned acts upon the whole splanchnic region. Another recent fillip to the study of the peripheral circulation has been given by the discovery of adrenalin, from a study of whose action upon the brain, heart and lungs, Sir James inferred the absence of vasomotor nerves. From that observation it follows that the circulation in all these organs has to be maintained by the heart alone, that is, independently of any regulating centre. Incidentally the condition is one that may profoundly affect the action of various drugs. An interesting explanation was given of the occurrence of cold feet in bed, and its proper remedy was shown to consist in elevating head and shoulders to raise the arterial and capillary pressure in the lower extremities. Sir James Barr emphasised the familiar precept that a man is as old as his arteries, and that after the age of fifty arterio-sclerosis directly or indirectly kills more people than any other disease. The whole address is characteristic of the philosophical researches undertaken by the modern physician in his pursuit of knowledge. Its suggestive value is incalculable, both as a stimulus and an example to others labouring in the same field. It affords, indeed, a fine example of the species of laborious investigation which in the hands of British observers has from time to time yielded brilliant results, and which, in earlier days, laid the scientific foundation of modern medicine in the discovery of the circulation of the blood.

NOTES ON CURRENT TOPICS.

"Truth" and Mr. Sewill's Offer.

We are thankful to note that Mr. Sewill's offer to start a guarantee fund for the collection of evidence against quackery has not passed unnoticed. The editor of *Truth*, with whom we have once at least found ourselves in conflict, is animated like ourselves with disgust for the thieving knaves who batten on the imbecility of their countrymen, and more than any other person he has been instrumental in bringing several of these rogues to justice. He confesses that he is unable always to see eye to eye with us, which is unfortunately the fact, but at the same time we note with great satisfaction that he, too, is in favour of the appointment of a Royal Commission to investigate the ways of quacks and quackery, and that he is prepared to support Mr. Sewill's suggestion. In the last number of *Truth* he tells us that almost single-handed as far as the lay press is concerned he has fought the evil of quackery, and that if a Royal Commission were appointed he fancies he has sufficient evidence to keep them employed for a month or two. Knowing that Mr. Labouchere is a fighting man, we cordially welcome his co-operation, and knowing that he is better cognisant of the ways of society pests than anyone else, we feel his support is better worth having than that of any other individual. If he will help us to get an independent inquiry which will turn the searchlight of truth into the tricks of the parasites who suck a livelihood out of the misfortunes of their fellow-creatures, we are quite prepared to sink differences on points of detail. If it were generally known that the bulk of advertising quacks are blackguards of the lowest type, who find in quackery the easiest way to a comfortable living, the public might not be so eager to believe the barefaced lies that many of our contemporaries purvey in their advertisement columns.

Dr. Freyberger and Goats' Milk.

Dr. Freyberger reminds us of the Irishman who never opened his mouth without putting his foot in it. A certain perverse fate seems to dog his footsteps, and he is hardly out of hot water with one set of persons than he is in it with another. In a recent inquest on a six months old child at Battersea he was called to give evidence, presumably because that district did not contain a practitioner who was capable of making a post-mortem on a case of "malnutrition." In his evidence Dr. Freyberger is reported to have said that "death was due to malnutrition, and that goats' milk, on which the child had been fed, was worse than skimmed milk, and did not contain sufficient fat or sugar." It would certainly take an expert pathologist who had no knowledge of medicine, hygiene, or dietetics to make so fatuous a statement, and if Dr. Freyberger is to continue frequently to be called in by Mr. Troutbeck he would do well to read an elementary text-book on the subject of milk. If he will compare the analysis of goats' milk with that of skimmed milk he will find he has made himself the laughing-stock of those who, though they have not become "expert pathologists," have at least retained the elements of practical medical knowledge.

The Corporation of Dublin and Consumptive Sanatoria.

At a special meeting of the Corporation of Dublin, held during the past week, it was decided to join with the Urban Councils and Rural District Councils of County Dublin in the erection of a sanatorium for consumptives on the chalet system, and to levy for that purpose a rate not exceeding one penny in the pound. Alderman Bergin, who proposed the resolution sanctioning the scheme, in the course of his speech read statistics bearing on the enormously high death rate from consumption in Dublin. He showed that while the death-rate for the whole of Ireland was 2·9 per thousand, the death rate for Leinster was 3·3 per thousand, and for Dublin 4·7 per thousand. He estimated that on a rate of a penny in the pound it would be possible in the first year to acquire a site to build forty chalets, and to maintain the patients therein, and in the second year to double the number of chalets. It was further pointed out that, if at any time the scheme became too expensive, or if the chalets were considered unhealthy by the sanitary authorities, the sanatorium could be got

rid of by the simple process of burning it down. The scheme of the Corporation has met with a considerable amount of adverse criticism, mainly on the ground that it is merely another device for spending the ratepayers' money, though one gentleman indeed went so far as to say that it was a move on behalf of the medical profession. We fear that if the Corporation are subject to such criticisms they have only their past actions to blame. At the same time, in the present case, and on the supposition that they will carry out the work as a business undertaking and not as philanthropic enterprise for the benefit of their employés, we consider that they have acted properly. It would be alike unwise and impossible for the general hospitals of Dublin to admit large numbers of consumptive patients, and it is equally unwise to try to effect, and impossible to effect, any reduction in the preventible mortality of tuberculosis by means which allow the infected patient to act as a centre of dissemination in the midst of his family and neighbourhood. As we have said, we think that in theory the Corporation have acted wisely, and we trust that the practical outcome of their project will be such as to confound their critics.

Progressive Advertising.

WE find we have a contemporary called *Progressive Advertising*, and that in its opinion we, on July 25th, "waxed quite hysterical on the iniquity of one of the great dailies publishing an advertisement entitled "Startling Advance in the Cure of Disease—Medical Enthusiasm." The great daily in question was the *Standard*, a fact as to which *Progressive Advertising* is discreetly silent, and on the point whether we "waxed hysterical" we may inform our contemporary that hysteria is a disease in which the patient fails to be guided by reason, whilst our paragraph contained carefully expressed, weighty reasons why this advertisement should not have been inserted. If the editor of our contemporary will re-publish this paragraph entire in his columns we would willingly submit to the judgment of his readers whether our contention was reasonable or not. But the writer knows perfectly well that advertising of this kind is improper, for later on he proceeds to say "it is unfortunate that a tighter hand is not placed on these advertisements at their "port of entry," and it is equally clearly visible that he is trying by a piece of special pleading to defend a kind of progressive advertising that is indefensible. The trick of inserting paid advertisements so leaded out as to resemble ordinary reading matter is doubtless an advance on the old methods, but it is questionable whether it is an honest and straightforward advance, and it is unquestionable that when the headlines are worded in such a way as to convey an impression that should not exist, the ordinary non-hysterical Englishman has a short and emphatic word wherewith to characterise the performance. If the editor of *Progressive Advertising* is anxious to show people how to introduce legitimate business in a legitimate way, we invite him to take his stand by us in trying to put down those quack advertisements which disgrace legitimate newspaper business.

Hope Hospital Scandal.

RECENTLY we had occasion to comment on the alleged mismanagement of the Hope Hospital of the Salford Guardians. The Board, as the result of the outcry raised by the ratepayers, resolved to hold an inquiry into their own conduct, and they invited Holland, the dismissed attendant who raised the whole question, to give evidence. This Holland refused to do except at an open, independent investigation, and we must say in fairness to the guardians, who offered him his expenses and an allowance of a guinea, that his letter in reply thanking the Board for their kind offer of a "cheap trip," was not of a tone to impress one with the genuineness of his complaints. However, the special committee met, and finding they could not get on with their business, fell to abusing each other. Fortunately, however, they did not separate till they had passed a resolution asking for a Local Government Board inquiry, and this it may be hoped will be forthcoming. There is so much gross mismanagement of poor-law infirmaries that a few inquiries, even if they cost money, will probably have a stimulating and beneficial effect.

Transplanted Kidneys.

THE triumphs of modern surgeons, thanks to Listerian methods, are to be found written chiefly in the surgery of the internal organs. Take, for instance, the kidney, which has for years past been operated upon with a freedom and familiarity that twenty or thirty years ago would have savoured of the land of fables. Perhaps one of the most daring feats of modern surgery has been the decortication of the kidney as a remedy for chronic Bright's disease. Severe as the cure may be—for it is successful in some instances—it is the only chance of curing an otherwise incurable condition. From a recent announcement, however, made at the Toronto meeting of the British Medical Association, it appears that decortication is by no means the last word in kidney surgery. An American surgeon, Dr. Carroll, formerly of Chicago, and now of the Rockefeller University of New York, exhibited two cats and two dogs in whose bodies were transplanted kidneys. He stated that in each case the kidneys appeared to be performing their functions successfully. One dog had survived the operation for seventeen days and a cat for two months. It is obvious that these experiments open up a new field of surgery. Ever since the days of John Hunter, who successfully transplanted the spur of a cock into the comb of another cock, the subject of transplantation has possessed a peculiar fascination for surgeons. That the perfection of modern surgical methods immensely increases the possibilities of the process is shown by Dr. Carroll's interesting investigation.

What is the Proper Food for Babies?

"Improper diet" is admittedly a common cause of many more or less fleeting and some of the serious ailments of childhood. It is quite another matter, however, when the medical attendant is asked to say what constitutes right and proper food for an infant. At the same time the science of infant feeding is beginning to be more perfectly understood nowadays, and the average medical practitioner should have little difficulty in keeping himself abreast of advances in the subject. At any rate, it is an easy task to say what is not proper food for children of tender age. The secretary of the recently-founded London day nurseries stated the other day that porter and pickles, sausages, currant cake and plums were commonly given to infants. Upon remonstrating with one mother for giving bloaters to her baby, the indignant relative retorted that she (the secretary) knew nothing about it, and whereas the other was not even married she herself had "buried five." The professional moral to be drawn is that medical men should conduct a collective investigation into infant feeding and establish definite rules. The subject should be systematically taught to medical students. At present the helpless mother affords an easy prey to patent foods of all kinds and obnoxious feeding bottles, just as she is to a hundred and one soothing syrups, teething powders, and other more or less poisonous proprietary medicines

Sir Victor Horsley and Alcohol.

Sir Victor Horsley's speech at the luncheon given by the Dominion Temperance Association to the members attending the British Medical Association meeting at Toronto has "caught on" a good deal, to judge by the attitude of the press in this country. In paper after paper we have read leaders and articles on the subject, and needless to say they are as diverse in their comments as they are in their political complexions. The length to which Sir Victor Horsley went—he is reported to have said that the value of alcohol as a drug was *nil*—is further than most medical men would be prepared to go, and indeed it is not arguable at all that alcohol is a drug with specific properties of which the judicious physician can avail himself with advantage in certain emergencies. That alcohol as a remedy was ridiculously over-used by the older generations of physicians is as true as that blood-letting and leeching were ridiculously over-used, and we would go as far as to say that alcohol in a general way has probably done as much harm as good. On the other hand, it is—on the same analogy—beyond the reach of argument that alcohol, blood-letting, and leeching have their appropriate uses and convenient applications; and they should be appraised at their proper worth, no more and no less, by medical men and the public. It is highly satisfactory to learn that the expenditure on alcohol at the Edinburgh Royal Infirmary has fallen in twenty years from 13s. 6½d. per patient to 3s. 4½d., and that the expenditure on milk has proportionately risen; for ourselves, we should think that 3s. a year per patient would be quite a fair estimate for the alcohol needed in the usual way. It is hardly possible to believe that even so warm a temperance advocate as Sir Victor Horsley can have denied any value to alcohol.

Cowboy and Eye-Specialist.

What can be done by an energetic chief constable in the way of getting quacks convicted was shown on August 23rd by the officer holding that post at Barnsley. A certain ex-cowboy, Noel Cody by name, found that a far better time could be obtained by "curing" cataracts in Yorkshire than by rounding up stock on the Texas plains. He gave lectures and music-hall performances, and announced he was an eye-specialist who could cure cases which no doctor could touch. Needless to say, he abused the medical profession; that is always part of the game. Certain patients resorted to his rooms where he put drops in their eyes and licked out cataracts with his tongue. At this game he netted over £20 a week by his own confession. Luckily the chief constable of Barnsley was a man of action; he collected his evidence, arrested his cowboy, and got him six months for obtaining money on false pretences. As members of the British public, we may congratulate ourselves that the case was not tried before Mr. Justice Grantham.

PERSONAL.

Amongst those who received the honorary D.Sc. at Leeds last Saturday were Professor Ray Lankester, Professor Alfred Grandidier, of Paris, Professor Paul Pelseneer, of Ghent, Professor Heinrich Rubens, of Berlin, Sir W. H. Parkin, Dr. Heinrich Caro, of Mannheim, Professor Albin Hallen, of Paris, Professor C. Liebermann, of Berlin, and Dr. C. A. Von Martius, of Berlin.

The body of a gentleman believed to be Dr. John McCallum Stewart, of Smithston Asylum, Greenock, was found on the railway line near Carlisle on July 31st. He had apparently opened the outer door of the carriage in mistake for the door leading into the corridor. He succumbed later. He was travelling from Greenock to London.

On July 27th Dr. J. Stuart Nairne, honorary consulting surgeon at the Samaritan Hospital, was presented with a Japanese carved consulting chair and a cheque for £300, together with a silver tray for Mrs. Nairne.

Her Royal Highness Princess Henry of Battenberg presided at a meeting of the General Committee of the James Memorial Hospital at East Cowes, of which she is President.

The University of St. Petersburg has conferred its honorary membership on Sir Frederick Treves, Lord Rector of Aberdeen.

Dr. Wallace Pomeroy becomes District Surgeon of Brandfort, Orange River Colony, in succession to Dr. Last, who has resigned.

Mr. H. C. Pretty, M.R.C.S., L.R.C.P., is head of the batting averages and second in the bowling averages for the Northamptonshire County eleven this year.

A CLINICAL LECTURE
ON
SOME POINTS IN REGARD TO EMPYEMATA.

By HERBERT FRENCH, M.A., M.D.Oxon., M.R.C.P. Lond.,

Assistant Physician to, and Demonstrator of Morbid Anatomy at, Guy's Hospital.

GENTLEMEN,—I thought that to-day we would consider some points about empyemata. First, as to the causes of empyemata. An organism is the ultimate cause, and probably the most common organism in these cases is the pneumococcus. It is, however, necessary to diagnose the empyema before the special organism at work can be determined; and, therefore, I think a bacteriological classification of empyemata is not the best for clinical purposes. I think you will find it useful to divide the causes of empyemata into two main groups, namely:—

(1) The *common*,

(2) The *possible*, causes.

The *common* causes are not many. First and foremost, we have pneumococcal affections of the lung—lobar *pneumonia* and *bronchopneumonia*. Secondly, and rather less commonly, we have *phthisis*. Thirdly, especially in children, we have empyemata which develop with no apparent cause, unless it be *neglect* and dirtiness. Such empyemata are sometimes called primary, but it is not at all unlikely that there has been some unrecognised bronchopneumonia in many of these cases, whilst in others the micro-organism may have found ingress from spots or impetigo on the skin. These are all the common causes.

There are many ways in which you can divide up the *possible* causes, but certainly we put under the first heading *secondary to trouble in the lung*. Amongst these causes we have to repeat lobar-pneumonia, bronchopneumonia and phthisis, and to add such conditions as bronchiectasis, or conditions in which there is gangrene of the lung or septic bronchopneumonia, or growth in the lung, or obstructed bronchus, from any cause, with putrefaction of the secretion which accumulates behind the obstruction

We will take another heading. An empyema may be *secondary to some sepsis, near to, but outside, the pleura*, as, for example, to sub-diaphragmatic abscess from any cause, such as a leaking gastric ulcer or growth. An empyema might in a similar way be secondary to an appendicular abscess, or to pyosalpinx, or to perinephric abscess; it might be secondary to pus in connection with the vertebræ or spinal caries; it might be secondary to a suppurating focus in the mediastinum, due to some such cause as an ulcerating epithelioma of the œsophagus; it might be secondary to an abscess in connection with a rib, tuberculous or otherwise.

In addition to being secondary to actual collections of pus near the pleural cavity, an empyema may result from a *metastatic condition in which infective material may be conveyed to the pleura from a distance through the blood-stream*, as in cases of osteomyelitis, or uterine sepsis after labour, or a simple effusion may become septic by infection with organisms absorbed from a boil, a whitlow, from pyorrhœa alveolaris, or from any other focus in some part away from the lung altogether.

(a) Lecture delivered at Guy's Hospital on Wednesday, June 6th.

There is another group of cases in which people who are ill with something entirely different may develop an empyema. For instance, a patient suffering from Bright's disease, or other *constitutional disorder*, may spontaneously develop an empyema, without there being any obvious source for the pleural infection.

When you have a case of empyema, always try to make up your mind what the cause is in that case. As evidence of the importance of not being content with merely diagnosing empyema, without also satisfying yourself as to the cause of it, I want to read you notes of a case that is now in Clinical. A woman, æt. 45, had been taken ill fourteen days before admission, with vomiting and diarrhœa. Four days later there was acute pain in the right side of the chest, and she was seen by two careful doctors, who thought that the signs indicated an empyema. They needled the chest, and found clear fluid with flakes of lymph in it. Following the needling, and over the area where it had been done, there developed a reddened, raised patch, which looked as if an abscess were forming under the skin, and the patient, who did not seem to be doing well, was sent up to the hospital. On admission there was a large tender fluctuating swelling behind, over the right side of the chest, reaching from the posterior axillary line to half an inch internal to the spine, and from the tenth rib to the angle of the scapula. Over that area there was a very impaired percussion note, with bronchial breathing. The cardiac impulse was half an inch outside the left nipple line. A needle was put in, pus was found; an anæsthetic was given, a rib resected, and the part having been drained, the patient was put back to bed. We had correctly diagnosed and treated an empyema; I am afraid we felt satisfied, without having decided why the empyema had come there. For the next week the temperature was perfectly normal, and there was no evidence that anything else was the matter with the patient. But on the ninth day there was a rigor, and the temperature went up, and a series of rigors, with high temperature, occurred on the five following days. The wound seemed to be draining perfectly well, and one thought of infective endocarditis or pyæmia. We could not find any cause for the rigors and the pyrexia. On the twelfth day after admission it was noticed by my clinical assistant, Mr. Davies, that the liver was one and a half inches lower than it had been. There were no signs of heart failure, so that the enlargement could not be due to passive engorgement. It looked as if the liver had been pushed down, and that there was pus underneath the diaphragm. Mr. R. P. Rowlands performed a second operation; he found the diaphragm pushed right up, so as almost to bulge into the opening made in draining the empyema. He incised the diaphragm, and found pus beneath it; on putting his fingers into the sub-diaphragmatic abscess cavity, he found these two renal calculi free in the pus. The case was primarily a calculus in

the kidney which had caused this perinephric subdiaphragmatic abscess which, in turn, had infected the pleura and brought on an empyema. It is noteworthy that there had been no definite symptoms of renal calculus in this case. It was found on careful subsequent inquiry that there had been an obscure attack of pain in the right side of the abdomen two years previously, without any urinary changes. There was no pus, nor any blood, in the urine when the patient was admitted for her empyema. One point, therefore, which you can learn from this case is that renal calculus may exist, and cause even a suppurative lesion, with practically no symptoms at all; but the main point that I wish you to remember is that the fact of there being an empyema does not finish your diagnosis; you must form your opinion as to the cause of the empyema before being satisfied.

I have an autopsy abstract of another case which illustrates that same point. The patient was a man, æt. 42, who, three weeks before admission, had a slight attack of pain which was referred to his right iliac fossa. He did not get well, being troubled with pain in the right side of the chest. He became dyspnœic, and had all the signs of a right-sided pleuritic effusion. He was tapped, and fifteen ounces of blood-stained serous fluid were drawn off a week before he died. His pain in the right side of the abdomen was thought to have been a referred one, from the inflamed pleura, though appendicitis was discussed. He got worse, and was explored again, but no pus was found. The case was diagnosed as one of very acute pleurisy, the acuteness accounting for the blood-stained effusion. He died, and at the autopsy we found that this man had had an appendicitis. The appendix was only slightly inflamed. Behind the ascending colon there was a kind of narrow rivulet of dirty lymph, and this rivulet opened into a sort of superficial lake of pus over the surface of the liver. There was no hole in the diaphragm, but above the diaphragm there were a good many ounces of clear serous effusion which compressed the lower lobe of the lung on the left side, and an older adhesion which shut the pleural cavity into two, and thus prevented a great collection of pus above the septum from getting down on to the diaphragm. In the same pleural cavity we had both a serous effusion and an empyema, separated from one another by inflammatory adhesions, but both due to infection of the pleura by pus below the diaphragm. Therefore, again I say, if you have a case of empyema, try to make up your mind what the cause of that empyema is.

You will remember that it is extremely rare for an infected pleura to give rise to peritonitis, whereas it is not at all uncommon for an infected peritoneum to give rise to pleurisy and empyema. It seems that this depends upon the fact that the lymphatic stream through the pores of the diaphragm is entirely from below upwards, and not from above downwards.

The next series of points that I want to touch upon are the physical signs that may arise from empyemata. These may be put into two main groups, namely :—

(1) Those *where the pus is* in its usual position, namely, *at the base of the lung.*

(2) Those *when the pus* is in some abnormal position, *not* at the base of the lung.

Remember that pulmonary physical signs depend entirely upon the physical condition of the lung. In the case of empyemata, the physical signs which you find are not due to the presence of pus, but to the fact that the pus expels the air from the surface parts of the lung.

The three main groups of *ordinary* physical signs that you get from empyemata differ according as there is (1) a small quantity of pus; (2) a medium quantity of pus; or (3) a great deal of pus. The physical signs when there is a great deal of pus in the usual position in a pleural cavity are easy to understand. The lung becomes completely airless from compression, so that there will be many negative signs; the affected side of the chest will not move properly with respiration; there will be no tactile vocal fremitus, no resonance, no entry, and therefore no vesicular murmur, no bronchial breathing, no rhonchi, no râles, no voice sounds; there will be two very important positive signs, namely —the intercostal spaces will be filled up, and the cardiac impulse will be displaced away from the affected lung.

When there is a good deal of pus, but not enough to express all the air from the upper part of the lung, we shall have similar physical signs, less in degree, but in addition we shall have skodaic resonance over the upper lobe, and, close to the upper border of the pus, here (shown on blackboard) we shall have compression of the alveoli, but not of the bronchial tubes, and may, therefore, expect a narrow strip of bronchial breathing with bronchophony, pectoriloquy, and very little ægophony.

It is in cases where, though the pus is at the base of the lung, its amount is *small*, that the chief difficulty as regards the interpretation of the physical signs arises. This is particularly so in children, because in children, I do not know why it is—the pus usually forms into a thin layer upon the surface of the lung, and, therefore, causes very little compression of the lung and the chest wall is so soft that an empyema can bulge the chest wall out as easily as it can push the lung in. The result is that there may be no compression even of the alveoli, and, therefore, notwithstanding the presence of pus, the physical signs may be the same as those given by the healthy lung. I must repeat what I have said before—the *presence of pus does not* by itself give rise to typical physical signs; if there are abnormal physical signs in these cases, it is because the physical condition of the lung is altered by compression by the pus. *If the pus does not compress air out of the lung*, there will be the usual resonance and the usual vesicular murmur. If the pus is in sufficient quantity to express the air from the alveoli, without compressing the bronchial tubes there will be physical signs exactly like those of confluent bronchopneumonia. At the affected base there will be somewhat impaired resonance, and on auscultation bronchial breathing will be heard, with bronchophony, pectoriloquy, and probably crackling râles. The pus will be insufficient to cause those two important positive physical signs of empyema, viz., displacement of the heart, and filling up of the intercostal spaces. Such cases are termed, sometimes, *latent* empyemata.

I have notes of a case of latent empyema at the base of the lung, which gave rise to the above physical signs. The patient was a child, æt. 7 months, who was suffering from dyspnœa, drowsiness, and loss of appetite. The child had well-marked rickets, pulse 164, temperature 103, respirations 50. The two sides of the chest were symmetrical, and resonant everywhere except over the right lower lobe, where it was impaired but not *dull*. Beware of calling notes dull; most notes described as dull are notes of impaired resonance. When you have any resonance left, there must be some air in the

lung. Over the area of impaired resonance there were bronchial breathing, fine râles and pectoriloquy, Over the rest of the lung there was puerile breathing without any râles at all. The dyspnœa became so great in that case, and the signs in the lung were so few, that tracheotomy was done, in the belief that there was diphtheritic obstruction to the larynx. This gave some relief, but the child died next day. From the right side of the chest four ounces of fluid pus were measured, in addition to some thick lymph; on the left side there were two ounces of pus and very thick lymph over the lung. The right lower lobe was compressed, with some bronchopneumonia, and the left side all over had patches of bronchopneumonia, none of which came to the surface. There you have a case in which pus was present in both sides of the chest, with bronchopneumonia, but the compression by the pus was so slight that there was not enough absence of air in the lung to give definite physical signs, and therefore a diagnosis of empyema was very difficult to make. Very often the only way in which you can diagnose a case of empyema in children is by exploring the chest with a hollow needle, and even then it is not always possible to discover the pus. It is important to try in every suspicious case, because the child is almost certain to die if the pus be not let out.

Is there any danger in needling the chest? "It hurts when the needle goes through the skin," is an objection to needling the chest, but by giving chloroform or ether you get over that. In most cases the patient is already so ill that the pain produced by the needle is but little felt. It is seldom that any anæsthetic, either local or general, is required. As to the production of a pneumothorax, it is very difficult to bring about that condition in a healthy man. If you tried to produce a pneumothorax in your next-door neighbour, you would have to take away a portion of the rib, and put your finger into the hole made, and between the two layers of pleura for nearly an inch all round the opening where the rib was taken away, before you could overcome the capillary cohesion of the two layers of pleura. It is not at all difficult to produce a pneumothorax in the chest if you have got the layers of pleura already separated, but if you have got the two layers well in contact, putting a needle through the pleura would not produce a pneumothorax.

So much for the physical signs when the empyema is at the base of the lung. Let us now consider some anomalous cases, in which the pus is elsewhere than at the base, being shut off by adhesions, and prevented from reaching the lowest part of the pleural cavity. It is clear that such empyemata may be almost anywhere; but there are four main headings under which they may be grouped, namely:—

(1) When the pus is loculated between the diaphragm and the lower lobe.

(2) When the pus is loculated between the lobes.

(3) When the pus is held up by a septum so as to be apical, or nearly apical, in position.

(4) When the pus is anterior to the lung, compressing the lung backwards.

These illustrations upon the blackboard (drawn by lecturer) will show you what I mean. I can also illustrate some of these conditions by cases, and by specimens from our museum.

I have here the notes of the case of a man, æt. 28, who came in complaining of being generally ill, and having profuse and foul expectoration at intervals. He had been hale and hearty up to nine months before admission. He was taken suddenly ill, with acute pain in the right side of his chest, and conveyed to Bow Infirmary, where he was laid up for seven weeks. The diagnosis was quite obscure. He improved, but he did not recover properly, and was brought here. His breath became very offensive and he began to expectorate foul matter in large quantities. During the nine months of his illness he lost 3st. in weight. He had got practically no abnormal physical signs at all. The chest was barrel-shaped and symmetrical, and moved well on respiration, with vocal fremitus on both sides, and fair vesicular murmur without râles. There was a case, then, of a man who had got something wrong with his chest, and who was bringing up a large quantity of foul sputum, and who was apparently suffering from some such affection as bronchiectasis, or a hidden empyema, or a sub-diapragmatic abscess, or gangrene of the lung. There were no physical signs to assist the diagnosis; gangrene of the lung was excluded by the absence of elastic fibres from the sputum. The temperature came down gradually, and a diagnosis of hidden empyema which had ruptured through the lung was made. A empyema may be hidden in two places. Supposing that you have the diaphragm adherent to the edges of the lower lobe of the lung, so that anything between the diaphragm and the pleura could not go forwards or backwards, it would then have to enlarge upwards, and there would be a collection of pus between the diaphragm and lung, giving rise to a supra-diaphragmatic abscess. There might be no abnormal physical signs at all. Then again, an empyema may be hidden between the two lobes of the lung; pus may collect there and compress a certain amount of the lung all round, but if it does not render the lung airless at the surface, there will be no abnormal physical signs. This man had got an empyema between the lobes which had ruptured into the lung, and given rise to the foulness of the sputum which he brought up.

I have here a specimen illustrating such a condition as that. There (shown by lecturer) is the empyema, and they have had to cut the lung in all directions to expose the inter-lobar septum and show where the empyema is. There have been three cases in the hospital during the last two years, with the physical signs exactly the same as in the case of that man.

This (other) specimen shows you a complete septum separating the pleural cavity into two entire halves, an upper and a lower pleural cavity, with pus in the one above, and none in the one below.

I will read you notes of an actual case of this. The patient was a boy, æt. 4, who had measles nine months before admission, and bronchitis ever since having that disease. Eventually his face began to swell, he brought up blood-stained sputum, was feverish, and lost appetite. On admission the pulse was 120, the temperature 99·2, respiration 60. The patient's face was swollen, he had marked cyanosis of the lips, and pains over the intercostal spaces. The left lung was dull from the apex to the base, with bronchial breathing, crackling râles, bronchophony, and pectoriloquy all over. The right upper and middle lobes were resonant, the right lower lobe was dull, with bronchial breathing and crackling râles all over it. The liver could be felt as low as the umbilicus. Both sides of the chest were explored in three places, but no pus was found. The child died the same night. An old pleurisy was found, and this formed a septum shutting off the lower part of the left pleural cavity from the upper,

which contained five ounces of pus. The right and left lower lobes were without any empyema at all, but were almost airless from confluent bronchopneumonia. Here, then, was an example of apical empyema, and it was a remarkably difficult condition to diagnose, but it is one that occurs from time to time. The mere fact of not finding pus with a needle is no proof that pus is not present.

I have got all kinds of specimens here to show you. Here is a lung, and you can see the upper and lower lobes, the posterior and anterior surfaces, and a septum between the two. Here we have a large cavity with a pyogenic membrane lining it in the *front* part of the lung. In this specimen the empyema is not behind, but in front, shut off by a vertical septum. What would be the physical signs in this case? As I have already said, physical signs are not due to pus being present, but to the pus making the lung contain no air. In this patient there was enough pus in the front of the chest to compress the lower lobe backwards, and make it as airless as if the pus had been behind compressing the lower lobe forwards and upwards. These diagrams (drawn on blackboard) will show you what I mean. The physical signs with pus here (shown) would be identical with the physical signs with pus there (shown). Therefore, if we percussed that patient, there would be complete dulness behind, just as much as if the pus were behind instead of in front. In that case there would be diagnosed quite certainly pus at the base, and a needle would be put in and no pus found. Why not? Because the needle would have to pass through skin, and muscles, and between the ribs, the parietal and visceral pleura, and then these two inches or more of compressed lower lobe (indicated on blackboard) before the needle entered the abscess cavity. You can miss the pus unless you put your needle in far enough—a very important thing to remember. It is remarkably difficult to discover pus with a needle in many cases. If you keep in mind the pictures of empyemata I have drawn for you, you will no longer be surprised at this, I think. Again, you will sometimes put a needle into the same hole, draw off clear fluid one time, and pus another time, within a few minutes of one another. The explanation is that there are loculi, and there has been a little difference in the direction in which the needle has been pointed in the two explorations; a serous loculus was first tapped, whilst the second time the end of the needle had entered a purulent loculus. Then again, if you have only a little pus in the chest you may go right through the pus, and unless you preserve a vacuum in the barrel of your syringe whilst you are drawing your needle out, you will get no pus. I have seen pus missed also by going in slowly. You require to put your needle in with a jerk. If you put your needle slowly into a pleural cavity, you may simply cause the pleura to bulge forward in front of the needle as a sort of cap to it, without its actually entering the empyema cavity at all.

There is one last point, and it is a thing to beware of. In dressing an empyema, do not let the drainage tube slip inside the pleural cavity. That may happen. I know a patient whose empyema did not seem to be healing up properly, and a second operation was done, and this time the tube which had been used at the first operation was removed from the pleural cavity.

I do not profess to have dealt in any way completely with the question of empyemata. The treatment is, of course, to let the pus out as soon as it is diagnosed. Diagnosis is the main thing. If you learn nothing else from our talk to-day, I would ask you to carry away in your mind at least two lasting impressions. The first is, that in addition to diagnosing empyema it is essential to try and make up your mind as to its cause. The second is that, whilst many cases have the most typical physical signs, there are very good reasons why, in other cases, the physical signs may not be at all those which you might at first think are essential to empyema.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week's number will be by G. Norman Meachen, M.D., B.S.Lond., M.R.C.P. Lond. and Edin., on "The Diagnosis and Treatment of Ringworm."*

ORIGINAL PAPERS.

THE PROGNOSIS OF PULMONARY TUBERCULOSIS.*

By J. J. S. LUCAS, M.D., B.A.Lond.,
Assistant Pathologist, Royal Infirmary, Bristol.

The subject I have chosen for this short paper is one which has been so much discussed by those more capable of forming opinions than I am, that you may consider it presumption on my part to do more than formulate their opinions, or at most to draw deductions from compilation of statistical results. I, however, do not intend to do this, but as I have possibly seen more pulmonary tuberculosis than any other serious disease, I am venturing to give you a few of the impressions I have formed and some of the various points I take into consideration in prognosing the future of a phthisical patient. Some of these have undoubtedly been impressed upon my mind by previous reading and confirmed by experience, while others may be erroneous and due to forming conclusions from peculiar groups of cases chance occasionally throws in one's way.

In the first place I will say that I have formed the opinion that it is unwise for a patient who has definitely had pulmonary tuberculosis to ever consider himself a sound man. Once a consumptive, always a consumptive. It is, I think, a very rare thing for a patient who has physical signs of lung tuberculosis and the presence of tubercle bacilli in his sputum to get well and remain perfectly well for many years while attending to his former occupation. A patient under sanatorium treatment may lose all his symptoms and the disease may remain quiescent for a long period, but sooner or later, more especially if he tends to drift into former habits, a relapse occurs which eventually may prove fatal. Within the last few months I have had five patients of this kind. All of them have broken down after having had no active physical signs or symptoms, not even a cough for more than a year—one for nearly four years. Three of these have got practically well again, one is improving to some extent, while the fifth is rapidly getting worse. I know, of course, that a large percentage of hospital *post mortems* show healed evidence of tuberculous mischief at an apex, but nearly all of these were not diagnosed, and a large number would have been undiagnosable due allowance being given for the shrinkage during

(*) Read at a meeting of the Bristol Medico-Chirurgical Society on February 14th, 1906.

the contraction in healing. It is certainly rare to find evidence of healed mischief beyond this such as would have been easily diagnosed, as, for instance, that which would have given infra-clavicular signs.

Having made a diagnosis, one of the most important points in influencing the prognosis is, I think, the appearance of the patient and the configuration of the chest. Anyone, by inhaling a sufficiently large dose of bacilli, may generate the disease, and I suppose the major portion of sanatorium patients are not of a typical phthisical appearance.

Persons, however, of the old tubercular and scrofulous types—especially the former, those with a lively temperament and long, narrow chests—unless they are most carefully looked after, do somehow or other develop consumption. In these the prognosis is certainly very bad. There seems, as a rule, no way of stopping the disease, and life is prolonged at the most only for a year or so. In these cases the constitution is generally hereditary, and if I examined a patient of this type and found only slight but definite indications of active tubercular mischief, I should tell his friends that in spite of treatment the patient would probably gradually lose ground and would never be fit again to resume his previous duties.

On the other hand, in a patient with a well-developed chest and prominent infra-clavicular regions, who had a good family history and who possibly had developed a tubercular patch on one of his lungs after extra hard or unhealthy work, I should be inclined, if there were no signs of great activity, to give the best of prognoses—viz., that with suitable treatment he would lose most, if not all, of his symptoms, and with care would probably live many years, and during that time would be capable of doing a good deal of useful work.

Of early symptoms two of the most suggestive of the further course of the disease are hæmoptysis and dyspepsia. In my experience hæmorrhage in the early stages generally indicates a chronic form. Very often, of course, no physical signs indicating phthisis can be found at first, but when they do assert themselves they seem to be of the fibroid type, and the disease tends to run a prolonged course with intervals of good health.

Dyspepsia, on the other hand, is a bad sign. Hygienic treatment may in some cases successfully combat this, but many of the cases cannot be checked, and persistent early indigestion, especially if attended by vomiting. is often the precursor of a progressive fatal illness.

A high temperature at one examination I do not consider of much importance as a rule. The exception is possibly a high temperature—say, 104°—in a patient who does not appreciate the fact, and only feels to be a " bit off colour." This is somewhat akin to the worst forms of typhoid and pneumonia. I have two recent cases in mind which may serve as examples. A doctor's daughter was going away from home to a boarding-school, and was dressed ready to go when I chanced to look in. Her mother asked me to see her before she went, as she was not feeling very well. I found her temperature to be 104°, and her sputum on examination showed tubercle bacilli. She only lived six months. A young fellow came to consult me for general malaise. He had a temperature over 103°, but no physical signs in his lungs. Bacilli were found in his sputum. A trained nurse he was living with at the time poo h poohed the idea of phthisis, and suggested his doctor was wrong. In spite of treatment, however, he has steadily lost health since, physical signs in both lungs have developed, and he is now in a precarious condition. The value of a regular temperature chart in treatment is too well known to need comment, and when under treatment an evening temperature two or more degrees above normal persists for a month the outlook is bad. I have certainly seen exceptions to this, but they are rare and may perhaps be said to prove the rule.

From the point of view of prognosis, the pulse, to my mind, is of more importance than the temperature. The first case of phthisis I saw in private practice was that of a young man with a pulse of 80 and a temperature over 100°. That was five years ago, and he is still alive and at work, and although he occasionally has remissions he is well enough to contemplate marriage (against my advice).

On the other hand, cases I have seen with a pulse more rapid than could be accounted for by the temperature, have almost invariably rapidly lost ground.

Of the commoner complications I should like to refer to the influence of laryngeal tuberculosis on the prognosis. From cases I have seen I should divide these cases into at least three varieties: (1) Ulceration of the cords alone, (2) swelling and ulceration of parts above the cord especially affecting the mucous membrane between the arytenoids, the ary-epiglottidean folds, and more rarely the epiglottis, and (3) general ulceration in the late stages of phthisis in which the trachea is often extensively involved with the other portions.

Ulceration of the cord alone does not appear to influence the prognosis. It sometimes occurs at the earliest stages, and I have certainly seen some cases get well.

Perhaps the commonest variety is swelling and ulceration in the outer arytenoid region. This is apt to spread and cause a good deal of huskiness in the voice, a certain amount of pain from involvement of the cartilages, and often dysphagia.

Nothing, as far as I know, can do much good for these, and the interesting point is that the lung physical signs are often masked. In Mr. Lake's book on " Laryngeal Phthisis," on the front page, is a drawing of a specimen I mounted of extensive laryngeal and tracheal ulceration. I remember perfectly well that a few days before this man died we could only find slight traces of disease in the lungs, but at the *post mortem* examination both were riddled with cavities. I have a similar case at the present time of a man dying with phthisis with a throat of this kind. Over six months ago his sputum was swarming with bacilli, and since then two doctors have told him his chest was intact. He is developing a few physical signs now, but I feel certain there is much more mischief than these indicate. Why this is so is probably due to small inlet of air into the lungs, and with a throat of this kind I generally conclude that the lungs are much worse than examination of them indicates, and that the prognosis is bad.

Before ending these disjointed remarks, I should like to briefly consider how the effect of treatment should influence the prognosis.

If after a few weeks' treatment there seems to be no improvement, but rather deterioration, a change of sanatorium is indicated; and if the result is similar, then after two or three different localities have been tried, it is perhaps better to allow the patient to please himself how he ekes out the last little bit of his wretched existence.

The majority, however, I suppose, improve for a time under hygienic treatment anywhere. In some this improvement is only transient, and a maximum is reached in a few weeks, with a steady decline in health afterwards. These patients are very unsatisfactory, and usually in them the prognosis is almost as bad as in those who do not improve at all. Another very annoying group of cases are those who are sent out of sanatoria "*cured*" or "*much improved*," who begin to lose ground directly they come home and resume their necessary duties, although generally under more improved conditions than before. This unfortunately includes a large portion of patients, and I have repeatedly had cases under my charge who have been sent home from sanatoria as well who succumbed in a few months to the disease. The only real test of satisfactory improvement is for patients to be able to live at their homes and to earn a livelihood for months without breaking down.

These, gentlemen, are a few of the points I consider in foretelling the future of a consumptive. They are, I know, far from complete, and purposely so. I have simply given a few ideas first hand, and have intentionally omitted the influence of concurrent diseases, and the effect on the prognosis of the amount of the tuberculous mischief and its position in the lungs. This is beyond the scope of the paper. The disease is a very deceptive one. Many accidents may happen, and it is unwise to be too definite. To make my remarks quite clear, I will end by enumerating the various points mentioned:—

1. A phthisical patient should never consider himself sound, at least not for some years, even after loss of all symptoms.

2. The appearance of the patient, the shape of his chest, and his family history are of the greatest importance in prognosis.

3. Of early symptoms hæmoptysis by itself is rather a good sign, while dyspepsia is a bad one.

4. Fever at one examination as a rule does not help the prognosis, but persistent evening temperature for a month is bad.

5. A rapid pulse is one of the worst of omens

6. Of throat complications, ulceration of th cords alone does not indicate much; swelling in the larynx is much more serious, and the physical signs in the lungs are often deceptive in these cases.

7. The effect of treatment can be gauged only by the condition of the patient several months after he has left the sanatorium and has undertaken duties he intends to perform for the rest of his life.

Addressing a jury at Clerkenwell Coroner's Court Mr. Walter Schröder said he found that where only one nurse-child was received for payment, and th foster-mother was consequently without the purview of the Infant Life Protection Act and unvisited by an inspector, the mortality was largely in excess of the cases under legal supervision.

A STUDY OF MORTALITY FROM DIARRHŒAL DISEASES AMONG INFANTS IN ENGLAND AND WALES. (*a*)

By THOMAS DIVINE, M.D., C.M. Glasg., D.P.H. Camb. and Lond., F.C.S.,

Late Assistant Medical Officer of Health, Huddersfield.

Under the heading "Diarrhœal Diseases" the Registrar-General includes deaths from epidemic diarrhœa, infective enteritis, ill-defined diarrhœa, gastric catarrh, other diseases of the stomach (mainly gastritis), enteritis and gastro-enteritis. These diseases were together in the year 1903 responsible for the death of 19,595 infants under one year of age, the death-rate being equal to 21 per 1,000 births for the whole of England and Wales. About 29 per cent. of the deaths occurred in the first three months of life; 34 per cent. at the age period, three to six months; and 37 per cent. between the age six and twelve months.

The following table (*b*) shows the diarrhœal death-rates of children under one year per 1,000 births in England and Wales, in urban and in rural counties, for each sex separately, and for both sexes together, in the quinquennium 1898-1902 and the corresponding rates for the year 1903:—

	Males.		Females.		Both.	
	1898–1902	1903	1898–1902	1903	1898–1902	1903
England and Wales	35	22	30	19	32	21
Urban Counties	39	26	35	23	37	24
Rura Counties	21	13	16	10	19	11

It will be observed that the rates in urban areas are about double those in rural; that the male rates are in excess of the female; and that the rates in 1903 are in every detail a marked improvement upon the averages of the preceding quinquennium.

The following table (*c*) shows the changes which have occurred in this rate from the quinquennium 1876-80 to the year 1903, the quinquennial periods being expressed as averages:—

England and Wales. Diarrhœal Diseases.

Period.	Deaths under One Year per 1,000 Births.
1876–80	17.0
1881–85	14.6
1886–90	17.5
1891–95	20.9
1896–1900	33.3
1901	34.5
1902	17.0
1903	20.9

The meteorological conditions in the years 1902 and 1903, it should be noted, were exceptionally favourable for a low rate from diarrhœa, and much of the improvement seen in those years had to be attributed to this circumstance. With these exceptions, however, it will be observed that the general tendency of the infantile diarrhœal death rate is towards a substantial increase; and this is most probably to be accounted for by the steady increase in artificial feeding during recent years.

It can be shown that, for the most part, the rate for diarrhœal diseases governs the infantile mortality figure for the year. For example, from the year 1876 to 1900, the lowest rate for diarrhœal diseases was 9 in 1879, and the highest 41·7 in 1899; and the corresponding infantile mortality figures were 135 and 163 respectively; these figures being the lowest but one, and the highest recorded during that period. So, too,

the favourable infantile mortality figures for the years 1902 and 1903 are due for the most part to a diminution in the rates for diarrhœal diseases; the infantile mortality rate of 1902 being 133, and that of 1903, 132.

The infantile death-rate from diarrhœal diseases possesses special interest for the sanitarian. It varies more widely in regard to place, season, and year than does any other infantile death-rate. It is in towns about double that which obtains in the country; late summer and early autumn are the special seasons of its incidence, aggravated in years of special heat and drought.

There can be no doubt that the principal cause of diarrhœa in infants is improper food. Out of nearly 2,000 fatal cases of diarrhœa recorded by Emmet Holt, only some 3 per cent. had been breast fed, and a similar result has been arrived at by Niven, of Manchester (*d*). Hope (*e*) in Liverpool, in 1899, which was a year of high diarrhœal mortality, found that among 1,096 deaths from diarrhœa 20·5 per cent. of the infants had been breast fed. Richards (*f*) found at Chesterfield that only 11 per cent. occurred among children fed from the breast; at Croydon he found the percentage to be 12. Newsholme, in Brighton, from the investigation of 191 fatal cases of diarrhœa in three years 1900-02. which were years of moderate diarrhœal mortality, found that 9·4 per cent. were breast fed (*g*); whilst of forty-four infantile deaths from diarrhœa in 1903, which was a year of low diarrhœal mortality, he found that only 6·8 per cent. of the infants had been entirely breast fed.(*h*)

Probably the explanation of these varying results is to be found in the natural history of the disorders, the breast-fed children being the last to suffer under the conditions generally favourable to diarrhœal mortality. At any rate, the figures amply demonstrate that hand feeding (and therefore it is to be feared improper feeding) is largely responsible.

The *raison d'être* of improper feeding practically opens up the whole question of the factors underlying infantile mortality in general, but here only a few special points in connection with the etiology of infantile diarrhœa need be briefly indicated.

Ballard first drew attention to the connection between earth temperature and diarrhœa. He pointed out in particular that the summer rise of diarrhœal mortality does not commence until the mean temperature recorded by the four-foot earth thermometer has attained somewhere about 56°F., no matter what may have been the temperature previously attained by the atmosphere or recorded by the one-foot earth thermometer; and he concluded that the essential cause of diarrhœa resides ordinarily in the superficial layers of the earth, where it is intimately associated with the life process of some micro-organism. This view has been very generally accepted until recent years. It fails, however, to completely explain the varying incidence of summer diarrhœa in children, and can therefore only be regarded as one of perhaps many other dominant factors. Waldo (*i*) considers that infantile diarrhœa must be regarded first and foremost as the result of strictly local conditions. Newsholme (*j*), after a careful examination of available data, has satisfied himself that the incidence of diarrhœa follows more closely the rainfall than the mean temperature of the air. He believes the relationship of rainfall and diarrhœa mortality to be so close that towns may be classified meteorologically in the order in which they ought to stand in reference to diarrhœa, and their true relative position as to domestic and municipal sanitation may be ascertained when we know whether they occupy a better or worse position on the list of towns than that which their meteorological place would indicate as rightly belonging to them. The greater the rainfall, especially in the third quarter of the year, the lower is the diarrhœal death-rate.

Waldo (*k*) suggests that diarrhœa is largely caused by the pollution of street dust by horse-dung. He says: "In casting around for a possible source of what may be regarded as a manifold infection of epidemic channels the idea occurred to me, as it has to others that organically polluted dust may be the vehicle of distribution. A further consideration of the circumstances of the case led me to the opinion that horse-dung may be the specific polluting material." Admitting this theory, the pollution of milk is readily understandable; the special incidence among hand-fed children is explained; and the decline of diarrhœa after rain (which lays the dust and washes away much of the poisonous material) follows naturally. Town dust is more highly charged with horse-dung than obtains in rural districts, and so the special incidence of infantile diarrhœa in towns is also explained.

Nash (*l*), whilst admitting the coincidence of a rise in earth temperature and diarrhœal mortality, joined issue with Ballard in his conclusion that the essential cause of diarrhœa is a specific micro-organism residing in the superficial layer of the earth whose vital manifestations are dependent upon conditions of season. He believed all evidence went to show that there is no one specific bacterium of diarrhœa. Nash advanced the hypothesis that the common house-fly is the principal cause of summer diarrhœa, and supported it by his experience of epidemic diarrhœa at Southend in the year 1902. During July and August there was no mortality among infants under one year from diarrhœa, as compared with twenty-three deaths during the same period of 1901. July and August of 1902 were comparatively cool months and rain fell on twenty-two out of the sixty-two days. The most remarkable phenomenon of these months was, however, the almost complete absence of *Musca domestica*. Niven (*m*), whilst emphasising the importance of other factors, considers it conceivable that house flies are a means of transmission and admits that the experience of Manchester in the year 1903 is in accordance with such an hypothesis.

All observers, however, are agreed that the essential and fundamental cause of epidemic diarrhœa is bacterial, and that in the case of infants the most common vehicle of this bacterial invasion is milk. It is probable that further bacteriological research will show that all of the factors, temperature, soil, dust, flies, play their part in its production, and that *the rainfall determines the degree* to which they operate.

Delépine (*n*) isolated from milk which caused an epidemic of diarrhœa several bacilli belonging to the colon group. Some of these were very virulent and closely resembled the bacillus enteritidis of Gaertner. In other cases he found a bacillus more closely resembling the bacillus coli of Escherich. He came to the conclusion that the varieties of those bacilli which are most important sources of infection are those which resemble the bacillus of Gaertner, and which therefore (and this is a point of much importance) produce *no permanent acidity, coagulation, or distinct smell when grown in milk*; so that absence of acidity in milk is not, as generally believed, an index of safety.

As regards the source of bacterial infection of milk, Delépine, while admitting that this might occur at the retailer's or in the consumer's home, believed (as the result of his experiments) that it more frequently occurred at the farm or (through vessels) in transit. Newsholme (*o*) on the other hand, is of opinion that milk is generally affected during storage at home in places where it is exposed to infective dust. He investigated the milk supply of 226 fatal cases of diarrhœa which occurred in Brighton in the three years 1900–2. In thirty-five of these cases the milk supply could not be ascertained, or (in four of the thirty-five cases) was derived from mixed sources. Of the remaining 191 cases, eighteen or 9·4 per cent., were breast-fed, and eighty-four, or 44 per cent. were fed on condensed milk. Thus, in over 53 per cent. of the cases of epidemic diarrhœa in Brighton with known milk supply, *domestic infection*, as far as milk is concerned, was alone possible. Great care was taken to exclude from these groups cases in which other sources of milk than the breast or condense d milk were on any occasion employed. The fact also that breast-fed children suffer from epidemic diarrhœa proves that infection

can occur in the home. Newsholme's observation, further, does away with the common belief that condensed milk is a safeguard against epidemic diarrhœa.

From the foregoing etiological considerations of infantile diarrhœa it can readily be understood that most, if not all of the associated factors act in the main through the agency of food; these are—overcrowding, imperfect ventilation, insanitary conditions in and around the house, want of personal cleanliness on the part of attendants and of the infant itself. The probability of insufficient clothing in predisposing to diarrhœa must also be borne in mind.

A high rate from infantile diarrhœa is almost regularly associated with adverse social, hygienic, and industrial conditions acting either directly or indirectly, and goes hand in hand with poverty, ignorance and neglect. The infantile death-rate from the diarrhœal diseases of the Registrar-General must, therefore, be regarded as indicating with peculiar sensitiveness the general hygienic conditions of any community, and above all, has to be taken as an index of the intelligence, solicitude and *morale* of mothers.

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL AND DISPENSARY.

Cases by Louis Vintras, M.D.

M.S., æt. 22., an anæmic looking young woman is a typical example of the minor breakdowns incidental to long hours, irregular feeding and much standing about, which are some of the inevitable concomitants of our strenuous latter-day life. She came as an out-patient three weeks ago, complaining of loss of appetite, pain in the region of the right ovary, general listlessness, headaches and inability to fix her attention on what she was doing. Her tongue was furred, her eyes were heavy, her lips dry, and there was some tenderness on pressure over the right ovary. She said that she was an assistant in a large shop, where she worked from 9 a.m. to 8 p.m., standing most of the day, and where meals were irregular in that the hours were changed from one week to another. She had been ill for about a week, but had continued at work; these poor workers cannot afford to rest, still less to be ill, and yet a little rest and a little treatment in time saves them so much trouble. This case was only one of anæmia, complicated by nervous prostration. She was put on citrate of iron and quinine and given every night a pill of aloes, belladonna and nux vomica. In about twelve days the tongue was cleaner, the eye brighter, the appetite better. She still complained, however, of headache, and so the treatment was reduced to a grain of quinine twice a day before meals. She is now rapidly improving. This case is one among thousands which show the utility of the out-patient department to which a few timely visits often suffices to check trouble which otherwise might prove serious. This is one of the aspects of the out-patients question which I think is not fully realised by the public at large.

The next patient, A.B., is a woman æt. 36, who works in furs and whose case is interesting from more than one point of view. Between the age of fourteen and fifteen she began to have epileptic fits, falling on the floor and biting her tongue; the fits were not very frequent, sometimes only two or three in a year, and they lasted until she was about 28, since when she has been free from them. She says that she was constantly under medical care during that period, and evidently received the best advice and with excellent results. This constitutes the first phase of her pathological history. The second phase overlapped the first, and began when she was twenty. She noticed then that her eyes grew rapidly tired, she could not read for long, and had a dull pain at the back of the eyeballs, especially the left. A chemist gave her some lotion, which, of course, did not improve matters, and she at last went to Moorfields. On examining her eyes it was found that the sight of the left eye was much impaired, and from what I could gather from her the case seems to have been one of retinitis. She was treated there for some time, and her eyes rapidly improved. She was subsequently given special lenses, which she wore until she was 24, when her sight was virtually so good that she had not needed to wear them since. The third phase of the patient's pathological history began in February, 1905, when after having suffered from violent headaches for several weeks she experienced intense and persistent thirst, and soon found that she was passing water more frequently and in greater quantity than before. She was treated for some time outside, but without relief, and in April came to the out-patients'. She was then passing five quarts of urine in the twenty-four hours, and the thirst was very troublesome. The amount of sugar in the water was comparatively small, and the polyuria was by far the most prominent symptom. She was put on small doses of arsenic, combined with soda and given a grain of blue pill combined with three grains of rhubarb pill every night. By July the quantity of urine passed had diminished to three quarts, by the end of August to two and three-quarter quarts, and by September 30th to two quarts and a half. She had then lost almost entirely the thirst annoyance, and was feeling well and active. For the last six weeks the arsenic had been replaced intermittently by the perchloride of iron mixture. She was so well then that she did not attend the out-patient department again until April of this year. When I then saw her she had a slight return of her symptoms, and the quantity of urine passed was again about two and a half quarts. There was a slight amount of sugar. She has been under treatment since, and is again improving. The quantity passed remains between two and two and a half quarts; the amount of sugar is very small, and the patient's general condition is fairly good. This case is interesting, (1st) in that it presents a perfect pathological sequence, extending over twenty-two years, and originating in some lesion of the brain and manifesting itself in three distinct ways, but all bearing an intimate relation to one another through their common origin. (2nd) The case also points strongly to the theory of the nervous origin of diabetes, a theory towards the establishment of which evidence is each day accumulating. A case I had recently in private practice illustrates this even more strikingly. A lady sub-let a detached part of her business premises, on arriving there one morning she was told that the tenant had not been seen for several days. She had the door forced open, and the man was found dead in the rooms, death having occurred several days before. A few days later she experienced intense thirst, pain in the loins and noticed that she was

passing an increased quantity of water. She came to me, and on examining her urine there was an appreciable quantity of sugar. The attack, which was the result of nervous shock, lasted for about three weeks, and disappeared completely under treatment.

The third case, J. R., is a pastry-cook, æt. 29. In October, 1900, he knocked his left foot against the inside of his right ankle, just behind the malleolus. The blow was followed by a bruise which was out of all proportion to so slight a blow, and his leg began to swell in the daytime. A chemist gave him some ointment, which he says caused the skin to break, and soon there was a large deep sore. He tried all sorts of things for it, and at last went to a hospital in Paris, where he was told the real cause of his trouble—deep varicose veins. With absolute rest and some soothing application the sore healed rapidly. Since he suffers from the fate of all those who have once developed varicose ulcers and whose occupation necessitates long standing; the skin breaks down every now and again, and the ulcer re-forms. It began again a couple of months ago, and is now the size of a sixpence. I only mention the cases as showing the importance of bearing in mind the possible existence of deep varicose veins, when the superficial veins are not enlarged, in the diagnosis of ulcers about the lower extremities.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL

NÆVUS OF LIP. — MR. PEYTON BEALE operated on an infant æt. 6 weeks, for an extensive and rapidly growing nævus involving practically the whole of the lower lip, extending beneath the mucous membrane and slightly beneath the skin. An incision was made along the lower lip for practically its whole length at the junction of the skin and mucous membrane; the latter was then dissected up freely and the nævoid tissue scraped away by means of a small sharp spoon. Two or three vessels required ligatures, but the oozing was less than would have been expected. All visible nævoid tissue having been thus removed, the flap of mucous membrane, consisting of practically the whole of the lip, was replaced and sutured in accurate position by means of a small curved needle and the finest catgut. Mr. Beale said that wherever it was possible a nævus which was spreading beneath the skin or mucous membrane, and which was not a cavernous nævus, should be freely excised, together with the skin or mucous membrane covering it. This, of course, was quite impossible in the region of the lip in the case of a nævus extending along its whole length. If the nævus were quite superficial, that is not extending deeper than the skin or mucous membrane, it might be treated by the application of pure carbolic or a very finely pointed actual cautery. If on the other hand the nævus was more deeply placed and was of a cavernous type, that is, consisting of spaces filled with blood, it was best treated by electrolysis, the negative pole being placed against the neck by means of a large moistened electrode and one or more steel needles insulated at their bases and connected with the positive pole being inserted into the nævus, a current of about 150 milliamperes being used for about twenty minutes. The case he had just operated upon, however, was not of either of these varieties, and he considered that the operation which he had done was the only thing possible, and he had adopted it in many similar cases with good results: the lifting up of a flap of skin or mucous membrane, scraping or dissecting away the nævoid tissue, and the replacement of the flap constituting the steps of this simple operation.

DISTENDED GALL BLADDER.—The same surgeon operated on a woman æt. about 50, who had an obviously enlarged gall bladder; it could easily be felt on palpating the abdomen, and moved with the liver during respiration. She was deeply jaundiced and complained of intense pain about the region of the gall bladder. She had had several previous attacks of jaundice accompanied with the same pain, and it was supposed that she had a gallstone impacted in the common duct. The abdomen was opened over the region of the gall bladder, and the latter was immediately seen, the part visible being as large as a goose's egg. Precautions were taken that as little as possible of its contents should find their way into the abdominal cavity, by packing the wound with gauze. The gall bladder was then freely opened; the fluid which escaped was of about the consistency of thick gum water, colourless and perfectly clear. The interior of the gall bladder was carefully examined by the finger and then by means of a long probe, but no stone or other source of obstruction could be felt. The gall bladder was then washed out and the hand passed into the abdominal cavity. The whole of the region at the back of the liver and round about the common bile duct and the duodenum was carefully explored, but no stone could be felt, nor could any cause of obstruction of the duct be made out. It was, however, noticed that there was a very ill defined "matting together" of all the tissues and structures at the back of the liver, and that the latter organ was actually pushed forwards as the result; the right kidney also appeared to be displaced through the same cause. The patient's condition did not admit of any thorough investigation, so the opening in the gall bladder was sewn up and the abdominal wall closed except where gauze drains were left around the gall bladder. Mr. Beale remarked that he was quite at a loss as to the cause of the obstruction in this case; it was clear that there must be something obstructing the bile duct and the common bile duct, for no bile was entering the gall bladder nor could the clear fluid within it escape.

The patient died two days after the operation, and at the post mortem examination it was ascertained that the matting together of the tissues which was felt at the back of the liver at the time of operation was due to the existence of a large ulcer in the duodenum. The ulcer was excised for microscopical examination, and from its size and from the appearance of its edges it was supposed to be malignant. In all probability the pain from which the patient suffered was due to the presence of the ulcer, although there were no other symptoms whatever pointing to its presence.

ROYAL FREE HOSPITAL.

TWO PRIMARY CARCINOMATA IN THE INTESTINAL TRACT.—MR. JOSEPH CUMMING operated on a man æt. 51, who had been admitted with the following symptoms:—During the last twelve months he had suffered from attacks of pain not confined to any special area of the abdomen, but radiating all over it; these attacks of pain lasted two or three days, and were accompanied by constipation and occasionally by vomiting; he never had attacks of diarrhœa, and never passed any blood. On examination, the man was rather thin, and looked ill; he had lost twelve pounds in weight in the last year. The abdomen was soft and not distended, and there was some tenderness in the epigastrium. During examination coils of intestine could be seen in peristaltic action, but no

lump could be felt anywhere in the abdomen. In view of these symptoms Mr. Cumming said he had come to the conclusion that the case was one of chronic intestinal obstruction, most probably due to a carcinoma. He pointed out the fact that a very common situation of carcinoma was the sigmoid, and that a common feature of growths in this neighbourhood was the impossibility of feeling them through the abdominal wall, owing to the small size of the growth, even when producing complete intestinal obstruction. There was nothing, he said, beyond probability to give any guidance as to the situation of the tumour. He intended after opening the abdomen to first examine the sigmoid; if he found nothing there, to trace the colon backwards until the site of obstruction was found; then, if the growth were removable, he proposed to excise it, if not to anastomose the intestine above the site of obstruction to the intestine below it, so as to relieve the symptoms. The abdomen was opened through the left rectus, and small intestine very much hypertrophied and dilated presented. The collapsed sigmoid was pulled up through the wound, but no sign of growth was found in it. However, on tracing it upwards, when the middle of the transverse colon was reached a tumour was found, but on bringing this out through the wound it was seen to be growing from the greater curvature of the stomach. There were some glands in the gastro-colic omentum, and the upper wall of the transverse colon was invaded with a small patch of growth. The removal of the growth was now considered possible, but, as there was nothing to account for the hypertrophy of the small intestine, further examination was deemed necessary before proceeding to perform such an extensive operation. On examining the region of the cæcum a second tumour, which was evidently the real cause of the obstruction, was found in the last foot of the ilium. For about two inches in this neighbourhood the intestine was converted into a hard cord about the thickness of a thumb, the gut above being dilated and the gut below collapsed. There was so much infiltration of the mesentery and of the mesenteric glands that it was impossible to think of excision, so a palliative operation only was decided upon. A lateral anastomosis was performed between the ilium and the sigmoid. This was rapidly done in the usual way by direct stitching, and the abdomen closed. Mr. Cumming remarked that this case showed very well the fact that it was wrong to wait until a tumour could be felt in the abdomen, if there were signs of chronic obstruction, such as this man presented. An extraordinary feature of this case, he pointed out, was that the patient had two separate and distinct primary growths. It also showed, he thought, how easily one might fall into error; supposing he had been content with finding the growth in the stomach without looking for the cause of the dilatation of the small intestine, then partial gastrectomy would have been performed, and the patient still left with intestinal obstruction. As had been seen, the anastomosis by direct stitching had only occupied thirteen minutes, this being very little longer than the time occupied in union with Murphy's button, but it had the advantages, he considered, of providing a very much bigger opening, a safer method of union and no mass of metal to get rid of.

The candidates elected to represent the Faculty of Medicine in the Standing Committee of the University of London are Miss Aldrich Blake, M.D., Dr. Sansom, and Miss Vaughan, M.D.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 26th, 1906.

Hiccough.

Hippocrates attributed, says M. Fiessenger in the *Journal des Practiciens*, a very sombre prognosis for obstinate hiccough; the opinion is certainly true in the case of imminent death. But hiccough in itself is not a very grave affair. It can be observed in the course of all kinds of maladies as a purely nervous symptom. Last year we were called to a patient in the country suffering from intense hiccough, a man who was seized with dyspeptic troubles accompanied with great pain. The spasmodic contractions followed in rapid succession for twenty-four hours. A warm bath for one hour and a few drops of a solution of morphine and atrophine quickly relieved him.

Each time that in the course of any malady hiccough appears, the attention of the attendant should be drawn to the degree of nervous excitability of the patient. Hysterical hiccough is well-known. It may last weeks or months, and disappear in the end abruptly or is replaced by some other manifestation of same origin. Persuasion and hydrotherapy will generally effect a cure. Besides this kind of hiccough of nervous origin, there exist several other causes, reflex or central.

The reflex causes generally observed are due to affections of the digestive tract, the peritoneum, the liver, urinary organs, lung, pleura, pericardium, peripheric nerves. The hiccough of gastro-intestinal origin is very frequent, especially in very young infants. It is due to an over-charged stomach, and which proper attention to the method of feeding will overcome. In adults hiccough is frequently due to dyspepsia from hyper-acidity of the stomach. The following solution acts frequently like a charm—

Hydroch. of morphia, 0·10 centigr.
Sulphate of atropine, 0·01 centigr.
Chloroform water, 12 grammes.

Three drops every two hours in a teaspoonful of water six to eight times in the twenty-four hours. The warm bath should be prolonged one hour. In ulcer of the stomach or cancer the same treatment can be used with benefit, and a small blister applied to the epigastrium, or an ice bag.

In peritonitis, hiccough is very frequent as well as in intestinal occlusion. For the former, repeated injections of small doses of morphia and the ice bag are the best treatment, while for the latter, belladonna should be given, as it acts both on the symptom and the malady.

Extract of belladonna, ¼ grain.

For one pill, one every hour for six hours, afterwards one every two hours.

Hiccough has been frequently observed in hepatic colic, especially in women. It can be relieved by a warm bath, the ice bag, and a mixture containing ether and morphia.

In certain maladies of the respiratory organs, pneumonia, laryngitis, whooping cough, asthma, pleurisy and particularly diaphragmatic pleurisy, hiccough is often a trouble to the patient, but yields to injection of morphia.

Hiccough of central origin is frequently emotional, and for which all kinds of remedies have been proposed with more or less success, a pinch of salt, or sugar steeped in vinegar on the tongue, forced inspiration, suspension of the respiration, compression of the wrists, projection of the tongue as far as possible out of the mouth, fright, etc.

The hiccough of certain infectious maladies is otherwise grave. That observed in typhoid fever is frequently accompanied by vomiting and the condition of the patient becomes imperilled; the same may be said of

scarlatina, scorbutus, cholera. Abundant drinks, baths (77 F.) injections of camphorated oil, and quinine constitute the treatment.

The hiccough of abundant hæmorrhage which precedes syncope, and that of cerebral affections (traumatisms, meningitis, cerebral hæmorrhage, tumours), is only a symptom and requires no special treatment.

In conclusion I will say that hiccough is only grave when it is accompanied by a very bad general condition of the patient.

CHRONIC METRITIS.

The following will be found a very efficient remedy:

Arseniate of soda, 1 gr.
Iodide of potassium, 1 drachm.
Water, 10 ounces.

Two tablespoonfuls a day for ten days, after which:

Ergot of Leigh, 3 gr.
Powder of Colombo } 5 gr.
Powder of Cinnamon }
Powder of carbonate of iron, 2 gr.

For one wafer; twice daily.

GERMANY.

Berlin, Aug. 26th, 1906.

AT the Freie Vereinigung der Chirurgen, Hr. Katzenstein discussed the

CHANGES IN THE CHEMISTRY OF THE STOMACH AFTER GASTRO-ENTEROSTOMY.

For the purpose of studying the question with greater exactitude he had found gastric fistula in dogs, and had then investigated the gastric processes before and after performing gastro enterostomy. He ascertained the following facts:

After all kinds of gastroenterostomy both bile and pancreatic juice freely found way into the stomach, in the earlier stages they were always present, but later only following certain phases of digestion.

The acidity of the stomach was distinctly reduced by the inflow of alkaline intestinal juices, first in consequence of chemical changes and then also of diminished formation of acids.

Pepsin in a neutral reaction was without activity: the ferment of albumen of the pancreatic juice, the trypsin, was only weakened by transient acid reaction; diastase and the ferment of fat acted also in an acid medium, but less powerfully than in an acid one. After gastro enterostomy, therefore, in the first instance, digestion was dependent on this resistent pancreatic ferment.

The secretion of pancreatic juice and of bile could be increased in a reflex manner by introduction of fat into the stomach (this had been observed also in the human subject).

In this way the acidity of the stomach can be reduced at will after gastro-enterostomy.

THE ÆTIOLOGY OF FATTY TISSUE-NECROSIS AND HEPATIC CHANGES AFTER INJURY OF THE PANCREAS.

A preliminary communication on this subject has recently been made by Professor Page and Dr. Martina, of Graz, in the *D. Zeitsch. f. Chir.*, 831 and 2. The authors say that although light has been thrown on the ætiology of necrosis of fatty tissue well known to follow injury to the pancreas, the subject in some of its aspects still remains in the dark.

The facts determined by the writers are:—(1) That the necrosis in question is caused, as a rule, by contact with the out-flowing pancreatic juice. The more the possibility of such contact is diminished the less necrosis there will be. Hæmorrhage into the fatty tissue precedes the action of the fat-splitting ferment. (2) The amount and rapidity of the necrosis are in direct proportion to the amount and quality of the food taken in. During digestion and copious ingestion of fat the necrosis is most marked; during fasting it is less, and continues so so long as food is withheld. (3) A small proportion of the necrosis met with during experiments on animals arose through embolisms, by invasion of the blood vessels by cells of the pancreas. Whether pancreatic cells could be conveyed in a similar manner along the lymph tracts with similar consequences, as stated by some, was not determined; but the author met with absolutely nothing that could lend support to such a view. Possibly the number of embolic necroses in the human subject was in consequence of easy vulnerability of the retro peritoneal situation of the pancreas, the firm capsule, the possibility of the close shutting off of the bursa omentalis as contrasted with the free entrance into the abdominal cavity. (4) The embolic necroses differed from those brought about by direct contact in various ways, amongst others by a later onset of the necroses. No time limit could be determined, but it appeared as if several days were required to bring them about, when necroses from contact were visible after two hours.

They were also localised in the immediate neighbourhood of a vein, so that at first they could only be seen on a section of it, and they did not reach the surface of the part affected. If the cell embolism was large, however, if there was much steapsin, and if a longer time had elapsed, they did appear on the surface, and they were then no longer distinguishable from contact necroses.

By the microscope also they were distinguished by the discovery of pancreas cells in the vein—these cells were found in clotted blood, sometimes individually, sometimes in accumulations. Valuable as this proof is it is not always positive, as the pancreas cells die off and become lost to sight if they remain long in a vein. A negative result, therefore, in a microscopical examination does not absolutely disprove an embolic origin.

Typical necrosis was induced by the injection of very finely saturated pancreas tissue into fatty tissue, or into the blood channels. The former always arose from contact, the latter in the immediate neighbourhood of the vein injected, and later on the fatty tissue adhering to it.

The liver showed great patchy changes both in the periphery and centre in the form of indistinct outline of acinus or complete absence of it. A part of these changes was almost certainly brought about by an embolic route, but the greater part by the pancreatic ferments reaching the liver in the blood.

To the objection that the experiments were performed under conditions not likely to be met with in the human subject, they point out that injury, hæmorrhage and inflammation might easily set up the conditions. Moreover the conditions for the development of fatty embolism and consequent fatty necrosis were more favourable in the human subject than in the animals experimented on.

In any case they must claim it as proved that fatty necrosis can be set up by embolisms.

AUSTRIA.

Vienna, Aug. 26th, 1906.

SCOPOLAMIN-MORPHIA INJECTIONS.

LOCAL anæsthesia has been the pursuit of many medical scientists of recent years, and still the subject is unsatisfactory to the surgeon. Rys, of Prague, records one of these experiments with scopolamin-morphia. Scopolamin is obtained from the root of a solanaceous plant, "Scopolia atropoides," or "Japonica" when obtained from the Japanese plant. It is an isomer of hyoscin, atropine, and hyoscyamin, with a formula of C_{17} H_{23} NO_3, and is an isomeric alkaloid of tropin. It is a mydriatic and sedative like atropine but shorter in duration. Scopolamin hydrobromic, has been used freely of late hypodermically as a sedative, and hypnotic, but its combination with morphia is in the experimental stage and requires a few victims before its value can be established.

Rys desired to remove a lymphoma from the neck of a youth, æt. 16, for which purpose he narcotised locally by injecting half a syringe full of a solution of scopolamin and morphia, which would contain 0·25 gramme of morphia and 0·01 of scopolamin hydrochlorate in 10·0 grammes of distilled water, *i.e.*, 3·85 grains of morphia, and 0·54 of scopolamin in two drachms of water. Seven minims of the solution would contain about a quarter of a grain of morphia and 7–6,000

of scopolamin. After the injection the boy went to sleep, but the pain of the operation speedily awoke him. In the course of an hour another injection was given and the operation completed with a little chloroform as he was very restless. The operation being over, the boy went to sleep, having received 0·77 grain of morphia and 0·015 of scopolamin. He slept quietly till four o'clock the following morning, when the nurse aroused the indoor physician to come at once, as the boy was having fits or convulsions, and she said he had never been awake since the operation the day before. The doctor found the lad in a deep sleep with reflex of body quite active, though absent in the cornea, and the pupils acting sluggishly. At short periods toxic convulsions were observed, breathing irregular, temperature 40·9° Cent., and pain on pressure over the body. To relieve the convulsions tincture of musk was injected with the desired effect of checking the spasms. The boy still slept, but the pulse was now very feeble and more rapid.

The physiological solution of salt was injected to the extent of 500 grammes, which improved the pulse for a time, but it speedily relapsed again into the weak condition. The salt solution was injected three times more with temporary improvement, while musk was used in the intervals, but the breathing still became weaker, which half an hour's artificial respiration did not improve. In spite of every effort the boy died about 11 o'clock, or twenty-four hours after the operation.

Rys thinks this should warn operators against using this local anæsthetic, as the above is not an isolated case of scopolamin-morphia narcosis.

Orthostatic Albuminuria.

Pelnak has recently been devoting his attention to the subject of albuminuria with the following results: Immediately the change of the body is made from the horizontal to the vertical, the arterial blood pressure is lowered and the pulse frequency increased, and remains so as long as the upright position is maintained; and during this period there is oliguria with increased specific gravity of the urine.

His experiments were conducted on sixteen young persons ranging from 12 years to 23, of which nine showed neuropathic symptoms and degenerative changes, being pale, with cardio-vascular irritation; seven suffered from the after effects of infectious disease, such as scarlet fever, etc. No symptom of renal disease was present in any of the cases, though six of them had hyaline and granular cylinders in the urine. None of them exceeded 2 per cent. of albumin.

As soon as the horizontal position was restored the pulse fell to its normal frequency with increased pressure without any dicrotism, which is usually present in the upright position. During this period the oliguria is converted into polyuria with a normal specific gravity. In order to confirm this low arterial blood pressure in connection with albuminuria he experimented with several drugs known to produce the desired effect, but all tended to prove the facts already stated. The blood pressure remained constant, the quantity of urine and chemical constituents remained the same. Cold baths made no change when movement of the body was prevented.

This pulse acceleration agrees with Thomayer—orthostatic tachycardia probably due to vasomotor irritability. The predisposing cause is neuro-asthenia or any weakness in the vasomotor system.

In all the cases examined the albumin disappeared from the urine as soon as the variation of pulse and blood pressure disappeared. The albumin is not permanent in the urine unless there is an anatomical cortical lesion in the kidney, but nothing of this sort existed in any of the cases operated on.

A young girl has died of cholera in Berlin. Measures have been taken to ensure the disinfection of the premises where the death occurred.

CONTINENTAL HEALTH RESORTS.

Aix-les-Bains.

[from our own correspondent.]

This Spa has a two-fold celebrity.

1st.—As a Mineral Water Station, justly renowned for the efficacy of its Springs, the beauty of its situation, its unquestioned sanitation and salubrity, the completeness of its Thermal Establishment, and the ability of its physicians.

2nd.—As a Pleasure Resort, unsurpassed in France for the variety of its summer entertainments and amusements.

In July and August its pleasure-seeking throngs out-number and throw into the shade its invalid *clientele;* but in May, June, September, and sometimes even early October (really the most agreeable months for climate here), the real *raison d'etre* of Aix-les-Bains has the predominance it merits. For after all, the genuine and enduring prosperity of Aix lies in its remedial waters, the inherited skilfulness of its masseurs, and the thorough knowledge of its medical practitioners of how best to use in each individual case its waters and appliances. Take away its Springs, Baths, and medical science, and the summer gaieties of Aix-les-Bains would fade away like the radiance of one of its lovely summer evenings.

It is well that its physicians do so thoroughly know what to do and what to leave undone; for, despite the many years' world-wide repute of Aix, every season invalids are sent here for treatment who should have been sent elsewhere. The profession who recommend patients to Continental baths sometimes overlook the *contre-indications* of each special Spa.

At Aix-les-Bains are two hot Springs, the Sulphur and the Alum Springs; the last really containing no alum. The two Springs combined supply to the bath establishment over 2,000,000 gallons every twenty-four hours. Both Springs are sulphurous, containing equal quantities of hydrogen, with additions of carbonates of iron, of magnesia, and of alumina. Their temperature varies from 110° to 115° Fahrenheit. By the Dupasquier sulphydrometre they show 4°. The treatment is essentially external, varying from many other thermal treatments by its massage under the douche. This *douche massage*, so far as Europe is concerned, originated here, and in its perfection is only administered here. Although imitated now in many places (where "Aix massage by Aix masseurs" is much advertised), the presence of a curious organic substance, *barégine*, gives to the waters here advantages in rubbing and kneading the muscular structure not found elsewhere.

The *Bouillon* (general vapour-bath) and the *Bertholet* (local vapour-bath) are also much utilized; the latter, named after a well-known Savoy chemist, and being peculiar to Aix-les-Bains.

The hill-side location and the arrangement of the Thermes afford to the physician precise control of temperatures and pressures, the pressure varying according to the position of the bath-rooms, the forms of these rooms being also designed to correspond with the kind of bath to be given therein.

At Marlioz (ten minutes from Aix) are cold sulphurous Springs, very efficacious in diseases of respiratory organs. Near the Public Park is an excellently equipped Zander Institute. And on heights around Aix are alkaline waters, growing in popularity more and more for table use and for internal lavages.

A dispute has arisen among the municipal authorities at Madrid on a question of public health. The sanitary commission ordered that 53 dairies in various parts of the capital should be closed, and the committee of the municipal council refused to agree. A great deal of feeling has been aroused by this action.

LETTERS TO THE EDITOR.

TRANSMISSION OF SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRFULAR.

SIR,—"An Average Practitioner," in this week's MEDICAL PRESS AND CIRCULAR, comments on Jonathan Hutchinson's lecture of last week, regarding "Transmission of Syphilis to the Third Generation."

Allow me a few words on this point not discussed by either of the gentlemen.

The history of syphilis in Japan (where I have had some practical experience with syphilitics of every class from the emperor's class to the outcast Eta (curly headed negroid) and the leper, even with the Aino, the white indigene of the Agricultural School Kaitokushi (of Hakodade), shows that there not only syphilis is transmitted to succeeding racial generations, but a measure of immunity as well. For 1,300 years at least that race has been saturated with syphilis. Syphilization has been honoured as a practice since the twelfth century of our Era, that is for seven hundred years. For then the Miniamota family captured all the Taira women (two rival families, for representation in the Mikado's office) and cast them into prostitution. Thus it came about that to seek one's wife, among the prostitutes, brought noble blood to one's family. Even the occurrence of syphilis in the prostitutes was considered a sign of nobility. Hence syphilization became significant of having Taira blood, in the family veins. Japanese reasoned that the family which was syphilized obtained a natural resistance to the disease. This theory, they also applied to vaccination and small-pox. It was this method of reasoning which provoked the greatest opposition to vaccination when introduced in 1849. A child of one who had had syphilis, or small-pox was not as apt to develop a virulent type of either disease when inoculated. Now, when an European is inoculated with the germ of syphilis of Japan he shows a virulent type of the disease, much more than does the Jap, who has been associated with syphilis for nine hundred years longer than the Western European, unless we count the lepers of the Madeleins of the crusade centuries as syphilitics and not lepers.

At any rate, Western Europe has known syphilis since 1472. while Japan has known it since the Korean and Mongol invasions. The Japanese have acquired a distinct measure of immunity against the ravages of the disease, if not against inoculation. Here is an advantage transmitted to the third and succeeding generations. Of course the Japanese have always been known for their Chinese teachings, the advantages of therapeutics, especially mercury, Kaifun (calomel), 724 A.D. Cinnabar (Chinese) fumigations. Corea nose stuffings of mercury as well as iodized sea-weed and other iodized foods and medicines. But they got, probably a large part of their good result of resistance to syphilis from the use of arsenic baths. Had the transmission of syphilis to the third generation been entirely malign, the Japanese race should have died out long ago, or it would have operated to make the race such a crowd of weaklings that it could not have accomplished anything of the kind that it was in its subsequent destiny.

The innate sensuality of this race of negroids, Malay and Mesopotamian Africans, mixed with the Negrotoid and Mongolian must have caused them to contract what Dr. Marshall, as quoted by Mr. Jonathan Hutchinson calls "primary syphilis" wholesale. Yet there does not seem to have resulted any rapid degeneration of the population due to it. I agree with Mr. Hutchinson entirely, the influence of syphilis on a population is very small, it is even born by the advantages. Of the antagonism or immunity transmitted to the new-generations. "It is not the cause of degeneration at all."

I am, Sir, yours truly,

ALBERT S. ASHMEAD, M.D.

New York, Aug. 16th, 1906.

THE FREE PORTRAIT TRICK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your comment on the "Free Portrait Trick" which appeared in your issue for August 15th, may I recount my experience *re* Mr. Tanqueray of Paris. I went through all the stages, that your colleague did, but unfortunately I went further. I purchased one of his frames, to be sent with the picture price £1 8s., which amount was to cover packing, carriage, etc. Although he had written previously to say that the magnificent photo was ready to forward, four weeks elapsed before it arrived, and then I had 5s. 3d. carriage to pay at the railway station. Of course I had no option but to pay, as I had already forwarded a cheque for the £1 8s. I got the station-master to write requesting this amount to be refunded. I wrote myself enclosing copies of his communication and threatening exposure if he did not pay, but no reply was ever received. I give you this information for publication, fearing that others may be duped in a similar way, and if I prevent the sale of one photo or frame it will be a satisfaction. Hoping you will find space for insertion of this communication.

I am, Sir, yours truly,

J. P. FALLS.

Red House, Carrick, Aug. 20th, 1906.

[Another correspondent informs us that in response to Tanqueray's circular he sent a photograph to him, and shortly received a notice saying his portrait was ready. Happening to be in Paris a few days later he called at Mr. Tanqueray's "studio" and asked to see it, saying he would take it away with him. He was told that it was undergoing some important finishing process and could not be seen just yet. A week or ten days later he called again, having in the meantime received another letter saying that his portrait was waiting and was very beautiful. However at the "studio" it was still invisible. Our correspondent then explained to Tanqueray what he thought of him, with the result that he got back the photograph which he had sent, but no portrait. Under the circumstances, we have no hesitation in warning those who may have received Tan queray's circulars to have no dealings with him.—ED.]

THE DECLINING BIRTH RATE.

To the Editor of the MEDICAL PRESS AND CIRFULAR.

SIR,—Your correspondent "Imperialist," need not I think regard with any concern those pessimistic preachers who are wont to be on the look out for some calamity, as I believe they are entirely off scent. So far from viewing this decline as detrimental there is greater reason, I fancy, to look upon the question as one for national, international, and in many instances individual congratulation. As a matter of fact, the evil which is supposed to exist does not in reality exist at all, simply because we may fairly infer that so long as the supply of population exceeds the demand, a condition which there is evidence to show at present exists, so long will it be to the advantage of the British Empire that some system of decimation should be at play; in other words, so long will it be necessary for our population to go on declining.

The evils which are imaginary in the declining birth rate, are not in reality centred in this decline. On the other hand, they are to be sought among the causes which underlie (these undoubtedly are serious and complex), and which induced or initiated this decline. It should therefore be the aim of those off scent, as I have remarked, to seek out such factors necessitating the decline, begging the question of necessity for one moment.

I have already stated that the supply of population is greater than the demand at the present day, and this notwithstanding the decline has been continuous and uninterrupted the last few decades. There is, I submit, incontrovertible evidence to prove this. This evidence consists of the fact that we are at the present moment face to face with a surplus and ever-increasing

population with which we are at our wits' end to know how to disgorge, these consisting of the unemployed and the unemployable. Further we have the evidence of General Booth and moreover the Church Army that emigration is the most effectual means to cope with the dilemma. This again means the exportation and drainage of the best blood from our own shores to foreign climes, the colonies, as might be expected, refusing the refuse. I ask, hypothetically, on the face of all this, what might have been the state of things had the ratio of population been reversed, that is to say, supposing increase had taken place in lieu of decrease during the period of decline. Surely, there is here sufficient evidence to prove the beneficial results of a declining birth-rate up to the present hour, without suggesting the suicidal policy of increase. If so, why lament its decline? It is certain nothing could paralyse or revolutionise any race, either highly civilised, or semi-civilised, and lead to degeneration sooner than an unmanageable and uncontrollable population.

In conclusion, sir, I am aware how frequently it is urged on grounds of political economy or sociology, that a declining birth rate affords index to the degeneracy of a race. This may be so in history. Even here the declension was probably concomitant with, rather than the cause of degeneracy. However, considerations of this kind are but moonshine with us. The British nation knows full well that numerical strength with her, except under very wide limits, counts for little or nothing; overruling territory so vast, it cannot be by virtue of number, but rather through moral and intellectual forces, whilst like the other leading powers of the world she derives her bodyguard from international jealousy and the great bone of contention, viz., the balance of power.

I am, Sir, yours truly,

Clement H. Sess.

Brighton, August 24th, 1906.

FANGO DI BATTAGLIA.

To the Editor of The Medical Press and Circular.

Sir,—Our attention has been drawn to a letter in your issue of Aug. 22nd, signed G. Harbinson, M.B., to the effect that the writer of the article on Matlock Bath was in error in stating that treatment by Fango di Battaglia can, at present, only be obtained at Matlock Bath. We can state, however, that he is substantially correct, because for the past three years we have only supplied Fango to the Royal Baths, at Matlock Bath, with the exception of small quantities for experimental purpose to hospitals, etc.

It is true that some three years ago we sent a small consignment to Smedley's Hydro, from which Institution Dr. Harbinson dates his letter, but we assume that this has long since disappeared. If the quantity sent has been, as your correspondent states, "in use for the last three years," we can only say that it must have long ago exhausted its usefulness, as it should be used only once and then thrown away.

It is so important that the treatment should be properly given, and that its supervision should be entirely in the hands of medical men, that we have preferred to limit its use either to the public baths of spas, or to establishments where we know the conditions to be quite favourable.

At Matlock Bath special provision has been made for Fango treatment; the mineral water is admirably adapted for storing it and the douches are arranged with special consideration to convenience in its administration.

As stated in your editorial note Fango is the Italian for "mud" and there are many kinds of Fango, but only one Fango di Battaglia. It is the mineral deposit from hot volcanic springs at Battaglia, and has been used continuously from the earliest ages for the relief of painful arthritis, neuralgia, etc. It is not to be compared with Fango which is supplied as a substitute and is often the mud from the bed of a river or pond The decayed organic matter and possible sewage contamination in these substitutes render them unsuitable and even dangerous.—I am, Sir, yours truly,

For the British Fango di Battaglia Co.,

G. Vetter, Manager.

Mark Lane, E.C., Aug. 27th, 1906.

OBITUARY.

THOMAS NEWBY, M.D., Lond.

Regretfully we announce the death of Dr. Thomas Newby. A native of Grimsby, having been born there some sixty-six years ago, he was sent first to Lord Brown's school. From there he proceeded to college, eventually taking his dgeree as M.D. at the London University.

One of the first public appointments he secured was that of Police Surgeon to the Borough Force, but on the town deciding in 1872 upon the necessity of a medical officer of health, he resigned that position, and became Grimsby's first medical officer, an appointment he held up to the time of his death. He was also the port medical officer, in which office he had the supervision of the cholera outbreak some years ago; he was the medical officer under the Aliens Act, and also medical officer to the Cleethorpes Urban District Council. The most striking feature of his medical character was his enthusiasm for sanitary reform. Dr. Newby was the oldest practitioner in practice in Grimsby, and his death, coming so soon after that of Dr. Allen's, has made a very big gap in the local medical ranks.

FRANKLIN HEWITT OLIVER, L.R.C.P., L.S.A.

Dr. Franklin Hewitt Oliver, of Kingsland-road and Clapton, a prominent medical practitioner in North-East London, died during last week at the premature age of 47. Dr. Oliver held numerous public appointments, including that of surgeon to the G and H divisions of the Metropolitan Police. He was one of the pathologists selected for London inquests, and was surgeon-accoucheur to the City of London Lying-In Hospital.

JAMES P. DRINKWATER, M.R.C.S., L.S.A.

Dr. James Pratchett Drinkwater, one of the best-known of the Welsh medical officers of health, died at Llangollen on August 23, at the age of 78. He had been medical officer to Llangollen Town Council for upwards of forty years, and held several other important public positions in the county. As a doctor in the service of the Cunard Company prior to settling in Wales, Dr. Drinkwater had crossed the Atlantic more than 100 times, and was well known to Transatlantic passengers, both in England and America. He took the M.R.C.S., Engl., in 1852, and the L.S.A. in 1862.

DR. MARGARET SMITH BELL, L.R.C.P., L.S.A.

Whilst spending a holiday at Portrush with her husband, Dr. J. Douglas Boyd, of Oldham, Dr. Margaret Smith Bell became seriously ill with a throat affection, and though two operations were performed at Belfast, she unfortunately died on August 21. Mrs. Bell was a daughter of a Newry gentleman. Graduating at the Irish colleges she came to Manchester in 1893 and built up a large practice. She became a co-opted member of the committee of the City Council in the registration of midwives, and was highly respected in the city by a large circle of friends.

JOHN CAMERON, M.D., F.R.C.P.

Dr. John Cameron has died at his residence at Liverpool at the age of 88. Dr. Cameron studied at Dublin and Glasgow and qualified as a licentiate of the Royal College of Surgeons, Edinburgh, in 1839, and took the M.D. degree at Glasgow in 1843. In 1859 he was admitted a member of the Royal College of Physicians, London, and in 1873 elected a Fellow.

MEDICAL NEWS IN BRIEF.

Honours for British Medical Men.

AT a special convocation of the University of Toronto the honorary degree of LL.D., *honoris causa*, was conferred upon Professor Thomas Clifford Allbutt, A. H. Freeland Barbour, Sir Thomas Barlow, Sir James Barr, Sir William Broadbent, George Cooper Franklin, William Dobinson Halliburton, Sir Victor Horsley, Donald MacAlister, William Julius Mickle; Louis Lapicque, Paris; Ludwig Aachoff, Marburg; and W. J Mayo, President of the American Medical Association. The degree was also conferred, *in absentia*, upon Dr. H. W. Langley Browne, chairman of the British Medical Council. Dr. George C. Franklin, Leicester, the retiring president, in acknowledging the honour on behalf of his associates in surgery, said they had found the techniques of antiseptic surgery in Canada to have reached a completeness and thoroughness which he hardly thought was to be found throughout England. He would go back to England knowing that the surgeons on this side of the Atlantic were among the very foremost of the world. It was announced that the McGill University, Montreal, would confer the degree of LL.D., *in absentia*, on Sir Thomas Barlow, Sir William Broadbent, Professor Allbutt, and Sir Victor Horsley.

Lord Cobham and the late Dr. Corbett's Estate.

THE annual meeting of subscribers to the Corbett Hospital, Stourbridge, was held at the Hospital on August 20th, the president (Viscount Cobham) being in the chair. The annual report of the Board of Management, after expressing regret at the death of the late Dr. Thomas Corbett, paid a tribute to the interest which that gentleman always took in the hospital. Lord Cobham, who moved the adoption of the reports, is one of the trustees under the late Dr. Thomas Corbett's will, and he made an important statement regarding the disposal of that part of the estate which had been left for philanthropic objects. The late Dr. Corbett, he said, had shown as great an interest in the hospital as did his brother, its founder, and when in his lifetime they brought before him plans for increasing the accommodation for women they felt confident that he would see them through the expense of the additional building entailed, and also through a great deal of the very heavy maintenance charges which such an extension meant. Unfortunately he died before matters could be arranged. Under the late Dr. Corbett's will there was a sum of money which was left for disposal by the trustees among charitable and philanthropic objects, and the Board of Management made a carefully prepared application for submission to the trustees. A very large sum of money, nearly £100,000, had been left to specified objects.

Death from Anthrax.

AT Bingley, on August 20th, an inquest was held on the body of George Garthwaite (56), wool-washer, who died at the Bingley Cottage Hospital, anthrax being suspected as the cause of death. Mr. T. C. Taylor, His Majesty's factory inspector, of Leeds, was present during the proceedings.

Margaret Garthwaite, the widow, stated that her husband had been employed by Messrs. G. Ackroyd, jun., commission wool-combers, Stanley Mills, Bingley, for the last four months, and had previously been a weaver. On Monday, the 13th inst., he complained to her of a pimple on his left wrist, but he went to his work that day. On the following morning the foreman, hearing something of this, examined the pimple, and then sent him to a doctor, and next day he was removed to the hospital.

Abraham Hird, the foreman at the works said that on Monday, the 13th inst., the deceased was handling East Indian wool, a kind which did not smell badly, and was rather greasy. The deceased had worked on East Indian and English wools and mohair.

Mr. George Ackroyd said he was a member of the Investigation Board in Bradford which was trying, at considerable cost, to find where the anthrax came from, and how it could be prevented. When this case occurred he consequently tried to find out what materials had passed through the man's hands, and he had had a list made of all the materials he might possibly have handled. These materials were East Indian wool, English wool—which were not injurious—and Cape mohair. The mohair had been sorted before received, except for one lot of mixed Cape mohair. This was received in bales, but many of these bales had been handled, having been made up of various lots and repacked. He believed the dustiest lot of material would be this Cape mohair, but none of the material was very dusty, and as far as smell went there would be no bad smell. As to the dust, he did not think it would be as stated, and could only appear to give a shower of dust if held up in sunlight. It was rarely that any sorting was done at his place, and none of this material was sorted, except that which was so dealt with after working. He added an expression of deep sympathy with the deceased's widow.

Dr. M. Crocker, of Bingley, said he was away when the deceased first came under treatment, and he first saw the man on the 17th inst. There was a typical pustule on the front of the left wrist, and from the first he had no doubt about the case being one of anthrax. He subsequently, from certain symptoms, formed the opinion that there was internal infection as well as local. The anti-serum and also the carbolic injection were tried, but the case was too far advanced.

Dr. Eurich, in his evidence, generally corroborated that of Dr. Crocker, and said that in his opinion the man died from internal anthrax, which he probably contracted by swallowing a germ.

The jury returned a verdict to the effect that death was due to internal anthrax.

West Wales Sanatorium.

A MEETING of the West Wales branch of the National Society for the Prevention of Consumption was held at Carmarthen Guildhall on August 21st, Sir James Williams-Drummond, Bart., Edwinsford, Lord Lieutenant of Carmarthenshire, presiding.

It having been mentioned that there were hopes of getting a £500 contribution as originally proposed, from the Carmarthenshire County Council, Mr. J. C. Harford, Falcondale, Lampeter, stated that the Cardiganshire County Council had practically received leave from the Local Government Board to advance £250 to the promoters of the sanatorium, and it was hoped the other two counties in West Wales would follow Cardiganshire's example. Dr. Bowen Jones, Carmarthen, one of the Hon Secretaries, in presenting the Finance Committee's report, showed that the estimated funds desired totalled £4,015 12s. 5d., the funds in hand when the committee met being £2,165 14s. 8d. That left a deficit of £1,849 17s. 9d. to be arranged for at the next general meeting.

Mr. Wheldon, treasurer, National Provincial Bank, Carmarthen, said they had now £1,165 in hand, another instalment of £1,000 having been paid to the contractor. The commission of the architect had also been met. £1,040 had to be found for those officials in October. They had to find some £500 or £1,000 for furnishing the building, and then talk about the maintenance fund. They were face to face with a serious problem, but this might be overcome if they put their shoulders to the wheel.

The furnishing of and maintaining the sanatorium was discussed at great length, and £1000 was individually guaranteed in the room, viz., £500 by Sir James and Lady Drummond, £200 by Mr. and Mrs. Trubshaw, £200 by Colonel Davies-Evans, Highmead (Lord-Lieutenant of Cardiganshire), and £100 by Colonel Morris, Garnant.

A guarantee fund of £2,000 having been formally opened on the motion of the chairman, Sir James Drummond remarked that no doubt Earl Cawdor, Sir James Hills-Johnes and Lady Hills-Johnes, and Mrs. Johnes would also become guarantors. It was understood that it was merely a nominal thing, it being felt that the money would be forthcoming when appeals were made. It was decided to ask the chief subscribers also to become guarantors, and to ask the clergy and ministers in West Wales to have special collections in their churches and chapels.

Goldfeld Again.

In the City of London Court, on August 22nd, an action was brought by Aaron Goldfeld, a German, giving an address in Falcon Square, Aldersgate Street, against Mr. Marcus Gunn, of Harley Street, to recover damages for "negligence at operation." The counsel for the defendant said the matter was *res juaicata* and the Court had no jurisdiction. The defendant was a well-known ophthalmic surgeon, and the plaintiff, in the name of Schleifstein, came to Moorfields Hospital suffering from hemianopia. He was operated upon in 1896, and nothing more was seen of him until May, 1904, when he came back to the hospital as Aaron Collins suffering from a detached retina. That was incurable. The plaintiff had recently lost his sight. He had brought three actions against the defendant, one in the Whitechapel County Court, another in the Bloomsbury County Court, and a third in the Shoreditch County Court. In all three the Judge had decided in favour of the defendant. Now the plaintiff had brought another action, and until the Attorney-General came back from his holiday there was no power to stop him. The plaintiff made a long statement to the Court in which he said all he wanted was justice. He had been to the hospital 50 or 60 times, and had undergone eight operations. His sight had been thoroughly destroyed. He was put under cocaine, not chloroform, and therefore he knew exactly what was done. He had been treated like an animal, and now the sight of both eyes had been destroyed. Judge Lumley Smith, K.C., said he was sorry for the plaintiff but he had no power to try the action over again. If the plaintiff liked to ask the County Court Judge for a new trial he might do so. He did not advise such an application. All he could do was to strike out the case with costs.

Sewage-Fed Mosquitos.

There is a perfect plague of mosquitos at Stonebridge Park, Harlesden. Several well-known residents are under treatment for blood-poisoning, set up by bites from these insects. The adjacent Brent Sewage Farm, belonging to the Willesden District Council, is said to be the origin of the trouble.

National Association Sanatorium.

The first sanatorium of the National Association formed to establish and maintain sanatoria for workers suffering from tuberculosis is being rapidly erected.

The building will probably be ready for the reception of patients at the end of the year. The site of the sanatorium is at Benenden, Kent, and is 700ft. above the sea level. No fewer than 252 acres have been acquired by the association.

The primary purpose of the movement is to treat workers in the earlier stages of tuberculosis, when cure is still practicable, and special attention will be paid to members of friendly societies. Over 32,000 postal employés have consented to contribute from their wages a certain sum for the maintenance of the establishment. The Post Office Sanatoria Association undertakes to endow 25 beds, the Hospital Sunday Fund five, the Club and Institute Union two, the Royal Oak Benefit Society one, the Foresters (South London Branch) one, the Amalgamated Society of Railway Servants one, and the National Union of Teachers two.

The building is to be constructed on a novel plan, "Frazzi" tiles being used on steel supports, and no brickwork being employed.

The building is to be self-supporting, and economy will be practised in the outdoor work of the patients which is part of the new system.

Doctor's Tragic Death.

At Lambeth Coroner's Court on August 25th, an inquest was held on the body of Dr. Charles Eardley Dumbleton, formerly medical officer of Singapore, who was found dead at St. Thomas's Home. William Barnes Chamberlain, said that Dr. Dumbleton, who was about fifty years of age, had resided lately at the Hampden Club, St. Pancras. He was a visiting surgeon at a hospital for skin diseases. Recently Dr. Dumbleton entered St. Thomas's Home. He had never threatened suicide, but had been troubled with sleeplessness. Nurse Everett said that Dr. Dumbleton had been under her care since she had been on night duty. He was very restless on Tuesday night, and in the morning when she took in his breakfast she found that he was not in his bed. She was told by another patient that he was asleep in another room. She went there and found him dead. Dr. Hedley, the resident medical officer of the Home, stated that Dr. Dumbleton was suffering from a swelling of both wrists, which was due to gout. He was expected to be quite well again in a few weeks. He had restless nights and was given drugs to induce sleep There would be pain in the wrists but that was relieved by hot fomentations applied at frequent intervals. On Tuesday night he seemed more cheerful than usual. From a *post mortem* examination it was found that the doctor had had malaria several times. Asphyxia from strangulation was the cause of death. A verdict of suicide whilst temporarily insane was returned.

Death from Hydrophobia.

A man named Albin Boehm, the owner of an estate at Promontor, near Buda-Pesth, died on August 23rd, of hydrophobia. Four weeks ago, while playing with a small dog, Boehm was bitten in the hand. The wound healed, and he thought no more of it. On Sunday of last week Boehm became unwell, and the doctors ascribed his illness to the bite. They sent Boehm to the Pasteur Institute at Buda-Pesth, where the symptoms of rabies were recognised, and the patient duly inoculated. Boehm subsequently returned home, and informed his wife that he was irretrievably lost. Boehm's condition became so much worse that he was conducted again the next day, in the company of two policemen, to the Pasteur Institute, and the doctors certified that nothing could be done. The unhappy man declared that he would die at home, so, with two strong attendants, he returned to Promontor, where he was placed in a separate room in his house. Thus until Tuesday, Boehm could speak through the door to his family and friends. Towards nine o'clock in the evening he became very weak, so he took to his bed, A violent attack seized him and caused his death soon afterwards.

Plague Mortality in India.

The Chief Plague Officer of India, in his report for 1905 shows that the deaths from plague have progressively doubled in each of the last three years In 1903 the deaths were 80,729; in the following years they were 166,620, and in 1905 they had risen to 305,737. Of the total number recorded for the last mentioned year 281,020 occurred in villages and towns under 50,000 inhabitants, only 24,717 deaths being registered in towns of 50,000 inhabitants or over. An active campaign against rats was carried on during the last four or five months of the year, and the report suggests that this was not without effect in lessening the spread of the disease, but at the same time it is recognised that to destroy all the rats in the villages is practically impossible, and that evacuation of the infected spot is the only remedy once the disease has manifested itself.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL LITERATURE.

The employment of Nitze's cystoscope when the bladder has been filled with air in the knee-chest-position is recommended for some conditions by Stoeckel (*Zentralbl. f. Gyn.*, No. 31, 1906). He says there are quite a number of cases in which the classical method of Nitze is not employable, especially when the bladder is defective (fistula) or incapable of holding the fluid injected to fill it, or too sensitive to allow of the injection of the fluid. Again where there is severe pyelitis the injected fluid rapidly becomes opaque if the pus escapes at all quickly from the ureter. For such cases his method is most valuable. It differs from the methods of Kelly and of Pawlik in that the Nitze cystoscope is used. The technique is difficult, the position of the patient uncomfortable, and there is danger of burning the wall of the bladder with the cystoscope lamp which rapidly becomes hot. Consequently the examiner must have had much experience in the use of the cystoscope before adopting this method. One can only recognise the urine from the ureters by the eddies it causes in the water-filled bladder, on the contrary when only air is present the thick stream itself shoots across the field of view as if it had been ejected from a syringe.

G.

The use of the rubber bag dilator in midwifery is reported on by Bürger (*Archiv. f. Gyn.*, Bd. lxxvii. Hft. 3) from observation of its employment in Schauta's Klinik. After describing the history of the development of the bag treatment, he gives a clear description of the mechanism of its action as it has already been demonstrated by others, especially von Bardeleben, and here, of course, its action is compared with that of the modern branched metallic dilators. The greatest service of the bag lies in its capability of being put to so many uses. It may not only be used for the induction of labour and strengthening of the uterine contractions, but also to prevent too early rupture of the bag of membranes, or as a substitute for the latter when it has already ruptured. It may thus be employed for the conduction of parturition without complications with the same advantages as when it is employed for accouchement forcé in eclampsia. Its use as a preventor of hæmorrhage in placenta prævia must also be remembered. Thus the bag has become a general friend to obstetricians, to which the simplicity of its technique has much conduced. The author then relates the good results obtained by Schauta. There are 147 cases which he describes in different groups according to the technique, which varies with the different indications for the use of the bag. The first class embraces those cases in which it was used before the onset of labour, the second when it was used after the onset of labour. In the first group there are sixteen cases of induction of labour and of abortion, in the majority of which other methods of induction had been tried in vain. To the second group belongs naturally the greatest number of cases, and among them particularly cases of eclampsia and placenta prævia. The statistics include 45 cases of eclampsia; 35 primiparæ, 10 multiparæ. In 21 cases there was not yet any appearance of labour, 31 cases had not come to full term, and 8 of the primiparæ were over 30 years of age. In 23 cases constant manual traction was applied to the bag. Incisions of the cervix were necessary in only 4 cases, and were made on account of its contraction about the after-coming head. In 4 cases the bag treatment failed. Regarding the question whether after insertion of the bag and the application of manual traction the fits were not increased, it may be mentioned that in 22 cases fits were still to be observed after labour was concluded, and that they were seen in only five cases during the action of the bag. Nine women out of the forty-five died. The puerperium of the survivors was free from fever in every case. The bag was used in 19 cases of placenta prævia. It must be reserved for the most difficult cases in which the dilatation of the os is not advanced enough for the employment of Braxton Hicks' version for fear of causing lacerations. Among 240 cases of placenta prævia Schauta's Klinik had 8 per cent. mortality. Among the 19 with bag treatment there were 3 deaths therefore more than 15 per cent. The author also cannot agree with Küstner and others that the bag treatment gives a lower infantile mortality. In placenta prævia the bag acts with greatest advantage at the commencement of labour as a preventor of hæmorrhage. In conclusion the author lays stress once more on the good qualities of the bag as a dilator, especially its physiological action as compared with metal dilators, and commends it as a most valuable help for general practitioners in difficult situations.

G.

Cervical lacerations in primiparæ. Scheurer (*Archiv. f. Gyn.*, Bd. lxxvii. Hft. 3) has examined the injuries to the cervix received during labour among newly delivered women and studied their ætiology. Ninety-nine primiparæ in the Frauenklinik Bern were examined by him soon after the expulsion of the placenta, and again when they were leaving the hospital. Following v. Bardeleben he divided the injuries into 4 groups. (1) complete lacerations of the cervix 13 cases; (2) large lacerations 13 cases; (3) moderate lacerations 46 cases; (4) notchings 27 cases. As regards the ætiology the most important cause is operative interference of every description. More than half the cases of complete laceration occurred in labours completed by operation. Abnormal presentations of the head are also an important causative factor. The average weight of the infants is in cases with severe lacerations more than 300 g. greater than in cases with small lacerations. Lacerations are also predisposed to by old age in primiparæ and by placenta prævia. The influence of premature rupture of the membranes and of contracted pelves could not be ascertained with certainty. The laceration is nearly always lateral, and in cases where there is one severe laceration or a more severe laceration on one side than the other, the right side is most frequently the one so affected. The relation between the position of the presenting part and the situation of the laceration could not be estimated. The largest lacerations were followed generally by little or no hæmorrhage. Whether there was any effect on the puerperal morbidity or the involution of the uterus could not be determined.

G.

Tuberculosis of the vulva according to Bonnin, Paris (*Zentralbl. f. Gyn*, No. 31, 1906), is usually secondary to genital or visceral tuberculosis. It may also be primary and may occur without infection of any other part of the generative system. The best known form is the ulcerative. The ulceration may be circumscribed, but it generally invades the larger and smaller labia, frequently also the perniæum and inner surface of the thigh. In addition to the ulcerative form there is another which is characterised by a pseudo-elephantiacal hypertrophy of the skin of the vulva without any ulceration. The microscope is necessary for the difficult diagnosis of this form. The prognosis is serious since the ulcerations always recur. It is especially grave in little girls

who frequently die of acute phthisis or secondary meningitis. The treatment of the ulcerative form consists in curettage and cauterisation, while the hypertrophic form must be extirpated.

G

The Causes of Sterility.—Ward (*Amer. Journal of Obst.*, August, 1906).—After referring to the low birth rate of America, Ward says that at the present day, with the attainment of the highest types of civilisation, we find, that instead of sterility being an opprobrium as in former years, it is often regarded as a boon by our fashionable women, but while voluntary "race suicide" is alarmingly prevalent, there is still that great multitude who, through no wish of their own, are childless, and spend their time and money in seeking relief. The sterility with which gynæcologists are specially concerned is that form which is attributable to some functional or organic defect in the woman which prevents child-bearing. There are four essential factors necessary to a conception: (1) the production of healthy spermatozoa; (2) the production of a healthy ovum; (3) the union of spermatozoa and ovum, and thus starting segmentation; (4) implantation of the fertilised ovum in the uterine mucosa. Various influences may temporarily suspend the function of ovulation. Debilitating or prolonged disease or a depressed state of the nervous system may be accompanied by amennorhœa and suppression of ovulation. The rheumatic or gouty diathesis, syphilis, alcoholism or drug addiction probably cause suppressed ovulation by reason of nutritive defects. The association of sterility with obesity is interesting, as there seems to be a direct relation between the ovarian function and fat formation; if the ovaries for any cause become functionally inactive or atrophied the woman is sterile and also obese. And Ward considers that the obesity is associated with the sterility as a result of the inactive ovaries, rather than the obesity being a cause of the sterility. Taking a broad view of the subject he does not consider flexions, displacements, neoplasms, &c., *per se*, as direct causes, but factors, and says if we look for the most common causes of endometritis and salpingo-oophoritis we will place our finger on the most prolific causes of acquired sterility. Gonorrhœa is the cause of perhaps 90 per cent. of the cases of septic salpingitis and of septic endometritis, and next to gonorrhœa he believes sepsis and subinvolution following abortion or labour are the important causes, especially of the so-called "one child" sterility. The cases of sterility associated with flexions, displacements, subinvolution, fibroids, &c., are due to not these conditions, *per se*, but to the associated chronic endometritis. In conclusion, we must be greatly impressed by the great importance of gonorrhœa in its relation to sterility when we remember it is nearly always responsible for sterility in the male, and as in nearly all instances of sterility in the woman due to gonorrhœa the infection has been innocently acquired by the wife from her husband, the fault lies with the man in more than two-thirds of all cases.

F.

Significance of Uterine Hæmorrhages of the Menopause.—Murray (*Amer. Jour. Obst.*, Aug., 1906). The author after revising the opinions of many writers asks the important questions:—Is an increased flow at the time of the menopause physiological? and is a hæmorrhage either that of menorrhagia or metrorrhagia merely functional and not a pathological condition? Duff in a paper on the subject reports the examination of 482 healthy women and only found 39 who gave a history of what could be termed hæmorrhage during the menopause, and only 5 gave a history of menorrhagia of any importance; Lockyer reports that out of 871 cases 662 gave no history of loss of blood and 208 had either menorrhagia, metrorrhagia, or a sanguineous discharge. Murray believes the normal change of life is established without an increased loss of blood, that the flow is less during the second decade of menstruation than the first, and less during the third than the second. At the period of cessation it decreases, coming slowly, less in amount of flow and less in the time occupied by the flow. In many cases the cessation of the menses has taken place without any intervals occurring between the regular times, but more frequently intervals of a month, two months, or more occur. The uterine hæmorrhages are often produced at the time by causes which obtain throughout the menstrual life of a woman, but which are more likely to give trouble when she is advanced in years or after frequent pregnancies or abortions—in fact this is the great reason why an excessive loss of blood has come to be considered concomitant with the menopause. Inflammatory conditions like cervicitis, endometritis, metritis, and the resulting hyperplasias come in this category, as do benign growths; polypi, fungoid endometritis, fibroids, fibroid infiltration, myofibrosis of the uterus, and diseases of the tubes and ovaries are conditions often found, and, lastly, hæmorrhage at this time is often a symptom of carcinoma.

F.

Typhoid Fever Occurring during Pregnancy.—Faulkrod (*Amer. Jour. of Obstetrics*, August. 1906). In recording observations of some cases of pregnancy complicated by typhoid fever, Faulkrod draws the following conclusions, without positively asserting them. The temperature records of the majority of cases are modified in some manner from those of typhoid not combined with pregnancy. Just as the mixed infection of typhoid and malaria may occur where the course of one or the other is modified during the height of the more toxic infection, so pregnancy and typhoid may be considered a mixed infection. After the growth and formation of the placenta, the blood of the mother generates in the serum-antibodies, which antagonise the invasion of syncytial tissue, and as the fœtus grows older the blood becomes more and more resistent to infection and we find the following to be true. In a typhoid infection occurring in a pregnant woman before the fourth month, the typhoid fever will prove the predominant infection, will develop a higher temperature than at a later date and the patient will, in as high as 85 per cent. of cases abort. The temperature and pulse, as a rule, fall at the inception of the pains and rise the day following delivery. In a typhoid infection occurring later than the sixth month the pregnancy will prove the stronger infection; the course of the typhoid will be modified greatly, and even at times so held in abeyance that the patients will not experience the slightest discomfort beyond the first symptoms of the infection. The temperature records prove of a flaccid weak type, the patients are relatively less toxic, and will usually carry the child to term. The question of the cause of abortion is interesting. No doubt, when the temperature ranges above 104° the fœtus or ovum cannot survive; also in fœtal infection it is right to suppose that perhaps the fœtus may die when the mother survives; but what causes the patient to abort after the temperature has reached normal and when, up to the day of abortion, she has appeared to be convalescing normally? The abortion must come from one of two sources: either the blood of the mother refuses to furnish food for the growing embryo, and also, as we above noted, furnish serum for antibodies, when already her cells are crowded with antityphoid serum, or again perhaps the antityphoid serum may also act as an antibody to the growing ovum; and second, is there not a possibility of some degeneration occurring in the endometrial tissue in a somewhat similar manner to the results of typhoid on the muscular and nervous tissue of other parts of the body, the uterus becoming not a fit ground for growth? Are we therefore led to believe that there is something generated by the pregnant woman which in a certain measure does protect her from the more virulent attack of the toxins of typhoid fever, and that the course of the fever is undoubtedly modified should it occur at such a period of pregnancy that the serum or cells have been charged with immunising bodies?

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

WITNESS.—You should not have accepted the 3s. without protest. By order of the Home Office "reasonable travelling expenses may be paid where the witness has to travel more than two miles to give evidence," though the "reasonableness" of the Home Office is generally third class.

ANTI-QUACKERY.—You compliment the laity too much in imagining there is any limit to their credulity. Only lately we met a lady who had paid 10s. 6d. for, and was wearing, an "anti-rheumatic" finger ring, and a sane, well-educated man carrying a potato in his pocket as a cure for sciatica.

AN ECHO OF THE RECENT CHRISTIAN SCIENCE TRIAL.

IT will be within the recollection of many of our readers that at the recent trial at the Old Bailey, in which Dr. Adcock was acquitted on a charge of malpractice, it was stated that the wound was dusted with ektogan. In view of the fatal result, not to mention the admitted sepsis of the sloughing bedsore, it seems only fair to state that ektogan, from its chemical composition, should be an excellent antiseptic preparation. It is a peroxide of zinc, containing about 10 per cent. active oxygen. The point is how it was used in Major White's case. Obviously it would be an absolute farce to sprinkle an antiseptic powder upon a large sloughing sore. The manufacturers are clearly entitled to protest against the injury that might result to their preparation without the added explanation.

DR. H. (Leeds).—Medical practitioners are required to notify to the Chief Inspector of Factories every case of mercurial poisoning contracted in a factory or workshop. A fee of 2s. 6d. is allowed for this. Dr. K. W. Goadby has written a good deal on the subject of lead anæmia, and all medical publishers keep a subject index to publications.

ANON (Chelsea).—We have applied our intelligence to the problem you set us, but are unable to solve it. Is it that we are obtuse, or is it that your argument is involved? Why not submit your idea to our readers' judgment?

PATENT MEDICINES AT THE CAPE.

Commenting on our recent exposures of patent medicine frauds and quackery in general, a subscriber at Cape Town, who is also a Member of the Cape of Good Hope House of Assembly, writes us that "ordinary inventions, such as the so-called 'patent medicines,' are protected here, as in England, for fourteen years only, but, in practice, the trade mark position of them means an indefinite monopoly. An effective remedy would be the limitation, or better still, the withdrawal altogether of this trade-mark protection." Our correspondent's letter contains other suggestions of considerable interest; he encloses also an official report of the "Select Committee on Quackery and Quack Medicines at the Cape," which we hope to deal with more fully in a subsequent number.

ET TU QUOQUE.—We will see what can be done in the matter. There is nothing unethical, as the letter with enclosure is sent to the profession only. It is however, a cheap way of getting an advertisement at the expense of a public institution.

J. O. H. S. will receive a private letter so soon as the necessary inquiries have been made.

LEGAL.—In most cases where a practice changes hands the purchaser takes over the vendor's house, either by way of purchase or by a lease for years. The conveyance is, however, drawn up in a separate document. You can get all information from *The Law of Medical Partnerships* (Barnard and Stocker).

Vacancies.

York County Hospital.—House Physician, with board, residence, and washing. Salary £100 per annum Applications to Fredk. Neden, Secretary and Manager, York.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer for the new Crossley Sanatorium, Delamere Forest, Cheshire. Salary £100 per annum, with board, apartments, and laundry. Resident Medical Officer for the Hospital, Bowdon, Cheshire. Salary £100 per annum, with board, apartments, laundry. Applications to C. W. Hunt. Secretary, Hardman Street, Deansgate, Manchester.

Chesterfield and North Derbyshire Hospital and Dispensary.—Senior House Surgeon. Salary £120 per annum, with board, apartments and laundress. Applications to the Secretary at the Hospital.

Dorchester County Asylum. — Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Walton Workhouse.—Resident Medical Officer. Salary £125 per annum, with board. Applications to Harris P. Cleaver, Union Clerk, Union Offices, Brougham Terrace, Liverpool.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Grey Hospital, King William's Town, Colony of the Cape of Good Hope.—Resident House Surgeon. Salary £300 per annum. Applications to the Agent-General for the Colony, 100 Victoria Street, Westminster, London.

Warrington Union Workhouse.—Resident Medical Officer. Salary £130 per annum, with apartments, rations, and other usual allowances. Applications to J. C. Sutton, Clerk to the Guardians, Bewsey Chambers, Warrington.

Royal Southern Hospital, Liverpool. — Resident Pathologist and Registrar. Salary £100 per annum, with board and residence. Applications to the Chairman of the Medical Board.

York Dispensary.—Resident Medical Officer. Salary £120 a year, with board, lodging, and attendance. Applications to W. Draper Esq., De Grey House, York.

Appointments.

BECKETT, F. H., M.B., B.C.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Ely District of the county of Cambridge.

EVANS, JOHN, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

SMYTH, RICHARD, M.D., M.Ch., M.A., T.C.D., Honorary Surgeon to the Ramsgate and St. Lawrence Dispensary.

Births.

HEALEY.—On Aug. 24th, at Ravenswood, Preston, the wife of Edridge Healey, M.B., of a daughter.

HOVENDEN.—On Aug. 25th, at Kitson Lodge, Barnes, the wife of Gerald S. Hovenden, M.D., B.S.(Lond.), M.R.C.S., of a son.

LISTER.—On Aug. 19th, at Terrington Lodge, King's Lynn, the wife of Septimus R. Lister, M.R.C.S., L.R.C.P., of a son.

MARSHALL.—On Aug. 20th, at Thorverton, Devon, the wife of C. de Z. Marshall, M.R.C.S., L.R.C.P., of a son.

MARTIN.—On Aug. 17th, at Blakau Mati, Singapore, the wife of Major Claude Buist Martin, R.A.M.C., of a daughter.

Marriages.

CHEYNEY—STUDDERT.—On Aug. 22nd, at St. Mary's Cathedral, Limerick, George Hammond Cheyney, M.R.C.S., L.R.C.P., son of the late Geo. J. Cheyney and Mrs. Cheyney, of Ware, Herts, to Gertrude Evelyn, third daughter of Mr. and Mrs. Jonas Studdert, of Kilkee, co. Clare, Ireland.

SIMKINS—SANDERS.—On Aug. 21st, at St. Mary's, Chigwell, William Almond, youngest son of the late Alfred Simkins, Carrington, Nottingham, to Ethel Mary, youngest daughter of the late Charles Sanders, M.D., and of Mrs. Sanders, The Haylands, Chigwell, Essex.

Deaths.

BRADDON.—On Aug. 23rd, at Troloss, Lanarkshire, John Vaudrey Braddon, B.A.Camb., J.P., of Leftwich House, Northwich, Cheshire, eldest son of the late C. H. Braddon, M.D., J.P., Cheetham Hill, Manchester.

CLIPPINGDALE.—On Aug. 23rd, at 50, Northfield Road, Stamford Hill, London, Rachel, widow of the late S. D. Clippingdale, surgeon, in her 88th year.

GIFFORD-BENNET.—On Aug. 21st, in London, Jane, widow of Dr. R. O. Gifford-Bennet, of Park Place, Buxton.

GRIMSHAW.—On Aug. 17th, at Friar's Hill, Wicklow, Elizabeth Dorothea, widow of Wrigley Grimshaw, Esq., F.R.C.S.I.

NAPPER.—On Aug. 22nd, at Broad Oak, Cranleigh, John Henry Napper, M.R.C.S., L.R.C.P., third surviving son of Albert Arthur Napper, surgeon, Cranleigh, in his 27th year.

ROUTH.—On Aug. 18th, at Springsure, Queensland, William Routh, M.R.C.S., L.R.C.P., only son of the late James Routh, of Wandsworth Common, S.W., in his 41st year.

NOTES AND COMMENTS.

Enteric Fever in Camp.

THE deaths of three promising young officers in Fleetwood Militia Camp cannot fail to serve a useful purpose by calling attention to the whole question of Army typhoid prevention both at home and abroad. If the Army surgeons cannot keep barracks and camps free from so preventable a malady when dealing with it on a small scale, and under the simplest and best conditions, how can they be expected to cope with the disease in the hurry and stress of a campaign? Elsewhere in our present issue we comment on the field always open for the Army surgeon in the investigation of enteric fever in home commands. Certain camps and barracks are notoriously the chosen abode of endemic typhoid. Any well-trained civilian expert, given time and the necessary means, would consider himself disgraced did he not rid such depots of the malady within a reasonable period. Why should not the stigma of incompetence apply equally to Army surgeons if they fail in a similar way? Director-General Keogh has done much in the way of post-graduate instruction of Army surgeons. Doubtless he has carefully considered the advisability of regular recurrent courses of instruction in civilian sanitary work.

Summer Diarrhœa.

THE month of August has been marked by epidemics of summer diarrhœa in various parts of the Kingdom. One of the interesting points about the malady is its strongly marked local incidence. Among the places that are suffering most severely is Birmingham, where the returns for successive weeks from diarrhœa have shown 19, 47, 86, and 112 deaths respectively. These figures point to a serious outbreak, and the subject is not unnaturally attracting a good deal of attention on the part of the civic authorities. In London the diarrhœa deaths for the four weeks mentioned have been 184, 285, 424, and 458. In Manchester during the same period they have numbered 17, 34, 80, and 113. The rapid increase has followed the usual rise in earth temperature, but this year the phenomenal heat is doubtless related closely to the increased severity. It seems somewhat curious that medical science, which has been in possession of so many data for so long a time, should summer after summer be compelled to fold its hands and gaze impotently upon a wholesale slaughter of our infantile population. Perhaps we have not secured sufficient data for generalisation in the framing of preventive measures. Anyway the continuance of the scourge is a reproach to practical hygiene.

Its Causes and its Remedies.

IT would be difficult to name a disease with more marked characteristics than this bane of the summer season. The first great fact is that it is essentially a disease of towns. Arguing from that point, Dr F. J. Waldo some years ago insisted that the disease was mainly due to the peculiar qualities of town dust, charged with bowel bacteria of the horse and other animals. That the disease is intimately connected with food contamination is generally admitted. Milk being the staple food of children, and being further specially liable to pollution of manifold kinds in the course of collection, distribution, and consumption, is naturally the most suspected agent. In many quarters the house-fly is held to be responsible for a deal of the damage. Possibly to the investigator one of the most reassuring and encouraging of all facts connected with summer diarrhœa is the practical immunity of breast-fed children. The irresistible inference is that the malady is conveyed by foodstuffs other than that supplied by Nature. To get rid of the disease means to purify effectually the air of towns and to educate the community generally as to the necessity of domestic hygiene and of scrupulous care in the storage and preparation of food.

The Irish University Question.

DURING the past fortnight the flow of letters on this subject has by no means diminished, but very little fresh light has been thrown upon it. The most important feature is perhaps the appearance of an increasing number of letters from Roman Catholics expressing a desire to see a re-casting of Trinity College. Amongst these may be mentioned two letters from members of the medical profession—Mr. Tobin, Surgeon to St. Vincent's Hospital, and Dr. Edward Magennis, M.D., R.U.I. Mr. Tobin is a retired member of the Army Medical Service, and at one time filled the post of Assistant Professor of Surgery in the Army Medical School. He expresses it as his opinion and as the result of his experience, whilst connected with the Army, that mutual intercourse, interests, and occupations, such as mixed education affords, are of value in forming

men's characters, and that it is right to give this fact due consideration before hastily condemning the so-called Trinity College scheme. Mr. Tobin re-echoes what we have already urged. Dr. Magennis' letter is written from the standpoint of a Catholic parent, who is anxious for a speedy, efficient, and equitable settlement of this vital question. He points out that no one can afford to despise the assets of Trinity College—its site, its buildings, and its world-wide traditions of learning. This suggests an interesting point. We objected to two universities because they would perpetuate strife. Even if it were possible to start the new on equal terms with the old this would be so, how much more will it be the case when the new is always conscious of an inferiority in prestige to its older rival. Another letter from a medical man—Dr. Laffan, of Cashel—appears in the daily press of Saturday last. It is, however, so intemperate in tone as to be far more injurious to the cause it would support than to that it would oppose.

LEADING ARTICLE.

IMPERIAL CANCER RESEARCH.

ANOTHER year's work of the Imperial Cancer Research Fund has gone by, and it is significant to notice how progress from the financial side is by no means commensurate with that on the scientific. The Cancer Research Fund is an undertaking the like of which has never been entered on before, in this country at all events, for it is the result of an attempt to endow purely scientific work sufficiently handsomely to allow no material objection to stand in the way of the best men being employed and the best work accomplished. And this without any directly utilitarian result being promised. Of course, a utilitarian object there is, and the work itself is eminently purposeful, but it would be mere charlatanry to inform the public that the prevention and cure of cancer would flow certainly and directly from the work of the Fund. The appeal for money should rest on the well-grounded hope that sound co-ordinated, scientific work will bring forth fruit in due time and on this ground only should subscriptions be solicited. It is sad, then, to notice from the report of the Fund that an appeal to the reason no less than to the imagination, of one's fellow-, countrymen, an appeal, too, for a comparatively modest sum, makes so little impression that the committee, in the fourth year of their existence, have been obliged to live partly on capital. A hundred and thirty thousand pounds was the sum the committee aimed at obtaining for a permanent endowment of the Fund, and some £80,000 was all they got originally, but with it they determined to start operations, hoping that new donors and subscribers would come forward. So, indeed, they have, for thirty-six new contributors have been found, but, on the other hand, no less than seventy-one old contributors have fallen out and the income of the Fund has suffered to the extent of more than £800. Taking into account the magnitude of the task the Fund has before it these numbers and these sums seem pitiably insufficient, and we still hope that the treasurer and the executive committee will see their way to "tap" the public pocket in some decisive and effective fashion. The number of people who realise that there is such a fund doing such work and needing money so badly, must be infinitesimal, and a judiciously-engineered campaign should certainly have a lasting effect on the prosperity of the Fund, especially if care were taken not to let the first flush of enthusiasm give way too rapidly to the apathy which is always likely to succeed it. It can well be impressed on the public that the researches carried on must necessarily be slow and arduous; in fact, at present, it may be said that little more than the establishment of the machinery and the clearing of the ground have been accomplished. The experimental investigations have all been directed so far to the ascertainment of quite elementary facts, such as whether malignant disease does exist in animals, and if its transference from animal to animal, and from man to animal, can be accomplished. Laborious as this task has been, far longer and more laborious ones have either recently been entered upon or still lie before the investigators. For instance, they have only just succeeded in obtaining offspring from mice suffering from cancer, a result which has taken three years to accomplish, and which is but a preliminary to the study of hereditary susceptibility. So, too, it took four years, and the examination of 100,000 mice to discover the occurrence of twenty-eight cases of spontaneous carcinoma of the mamma. One curious fact already ascertained by the work of the Fund is the extraordinary variability of the growth of transplanted carcinomas in mice, and if this be compared with the well-known clinical variations in the growth of cancerous tumours in man it is readily apparent that the key to the position may lie in research into the factors that contribute to this variability. Indeed, the task is already in hand, and attempts to modify the growth of tumours have been undertaken, and immunity in mice to inoculated tumours has been obtained by previous inoculation and by the injection of healthy blood. Altogether, it may be said that the prospects of substantial advance are brighter than they have ever been, and that if the public will only support the Fund with sufficient generosity a day of great things may be at hand.

NOTES ON CURRENT TOPICS.

American Spelling Again.

THE President of the United States and with him the spelling "Reform" Committee, whatever that may be, appear to have somewhat over-reached themselves. This masterful attempt to enforce new methods has been unanimously repudiated by the public press throughout the American continent. Spelling "reform" mania, however, is no new matter to the MEDICAL PRESS AND

Circular. Several years ago we first entered our protest against it, when certain practitioners of "Filadelfia," began to "reform" the spelling of medical terms. In this connection it is of especial interest to learn how obnoxious to the American educated public the clipping and lopping of English words generally has proved to be; indeed so much hostile feeling has been excited throughout the United States by the President's promulgation "ordering" these "reforms" that, in the opinion of the best authorities, nothing will be done. The public Press in the United States is entirely free and independent, and will not be "ordered" by anyone, not even by the President of the Republic. We could only wish that the great medical publishing houses of America would exhibit the same freedom and independence, and insist upon the editors of the journals that they control and the authors of the books which they publish adhering to the common usages of spelling which belong to the English language. Then their journals and books would soon become more popular in this country, and be more sought after by English medical men. Meanwhile, everyone who is interested in this subject will closely watch the progress of the opposition to the President's ukase. Possibly, however, the President now feels sorry that he ever took the matter up, and Mr. Carnegie is possibly sorry also that he diverted some of his funds from founding public libraries to trying to make all the books thereof obsolete.

Experiments on Patients.

The public have a just horror of being "experimented upon" when they are ill, and were they not fed with malignant misrepresentations by certain people who, having a weak case, find refuge in the time-honoured dodge of abusing the plaintiff's attorney, they would be satisfied by the assurance that in Great Britain the light of public opinion and, let us add the good feeling of the medical profession, make any "experiment" impossible. That is, "experiment" in the sense in which they use it, for every dose that is prescribed for every patient is an experiment, and it is obvious that the science of medicine could not advance if new drugs and new treatments were not tried. The whole point about an experiment on a patient is whether it has origin in a well-grounded belief that it not only will do the patient good, but that it offers him the best hope of relief. It appears that in Austria a certain number of men have been experimenting with Rontgen rays in various conditions, and Röntgen rays are now known not to be so free from risk as they were originally believed to be. Consequently, if we may believe reports to hand, a certain number of unfortunate results have occurred and public feeling has been aroused. The Austrian Minister of the Interior has therefore issued an order that hospital doctors are not to make scientific experiments on patients or to treat them with remedies the efficacy of which has not been tested. Exception, however, is made in favour of experiments involving questions of diagnosis, immunisation, and prophylaxis, so long as these are carried out in deference to the departmental heads and have bearing on patients' actual complaints. Antivivisectionists will please note that in this country, while it is rightly held to be inhuman to experiment on patients, it is regarded as necessary to test new procedures and new drugs on animals before applying them to man.

The Surgery of the Broken Neck.

The marvels of modern surgery have been once more impressed on the British public in the rescue of Mr. St. John Harmsworth from what is popularly known as a "broken neck." by the exposure, and rectification of a fractured sixth cervical vertebra. We congratulate both the patient and his friends heartily on this most gratifying result. At the same time medical men will not fail to recognise that the surgeon's part in the incident is mainly mechanical. Large fees are not grudged to the operative surgeon, but the physician has to be content with a guinea or two for a consultation before handing over his patient for operation. Yet it is the patient physician who by localising the functions of the brain and spinal cord has shown the surgeon what is wanted. The work of the physician from an intellectual standpoint is incomparably higher than that of the mere operative surgeon. Now and then, of course, a giant like Lister arises amongst the surgeons and makes advances that are registered in the annals of all succeeding ages, but he does it as a man of general science rather than as a surgeon. To a great extent the field of the consulting physician has been so encroached upon that he will probably have sooner or later to emerge in a new form, possibly as a compound surgeon-physician. Thus in the far future we may revert to the original conception of the medical man who is competent in all the wide branches of his profession.

Is Appendicitis on the Increase?

Human nature is given to gregarious action in its joys, its sorrows, its fashions, but most of all perhaps in its fears. No one has ever been able to say exactly why a crowd, for instance, should be suddenly swayed to derision, or laughter, or fierce anger, or wild panic. At the present moment the British public is settling down after a wild wave of popular resentment against American tinned goods. But some of our national fears, if less obtrusive are none the less real and persistent Take the case of appendicitis, a disease that was hardly recognised a dozen years ago. It is pretty safe to assert that few grown and sane citizens of the Empire have not had the fear of appendicitis at some time flit across their mental horizon. It is therefore to be desired that all medical utterances upon the subject should be guarded and accurate. Only the other day the statement ran the round of the newspaper press that of late appendicitis had largely multiplied and in proof thereof was cited the steady increase of deaths

from that disease in one of the largest London hospitals. As a matter of fact, the malady is every year more accurately diagnosed and consequently more operations take place. In former years cases of the kind, not being then recognised, were ascribed to cold, inflammation, and other more or less vague causes. As a matter of fact, there is nothing to show that appendicitis is on the increase but a good deal to prove that a vast proportion of cases are curable if detected by the surgeon in good time.

Science as Moloch.

THE report of the wonderfully successful experiments of Dr. Alexis Carrell in the transplantation of the kidneys of animals has stirred the anti-vivisectionist professional writers into a state of indignation, and a good many articles have been let off on the subject. It is possible to take these writers too seriously, for they so obviously write to their brief that we guess most of their own supporters do not find their faith much strengthened by the stuff provided for them. An average sample of the argument provided in writings of this kind is to be found in a leading article in the *Morning Leader* for August 27th, entitled "The Moloch of Science." It begins by reciting the horrors of priestly tyranny over men's minds in earlier civilisations, and then goes on to point out how modern Europe has long been under the iron heel of medical tyranny, examples of which are found in laws to cleanse oysters' beards, and not to eat too much asparagus. We confess that we know little about the former, so that we fear either to endorse or to contradict this important injunction, but we should have thought medical teaching was not needed to let a man know that to eat too much of anything was not good. After these striking examples of the awful tyranny the public are subjected to, the writer proceeds to dwell upon the grim and foul superstitions which found vent in Dr. Carrell's experiments. The only conceivable excuses for the mutilation of helpless animals would be a plea that human suffering would be alleviated thereby, and Dr. Carrell and his associates have no such plea to offer. Is it demanding too much of the capacity of a writer of this type to ask him to follow the argument that if kidneys can be successfully transplanted from animal to animal it may be found possible to do so from animal to man? And that chronic nephritis is an incurable disease? A man who cannot take so small a step in reasoning for himself, and yet writes of "sheer wanton cruelty no shambles can offer any parallel to," makes one fear that the tyranny the future has to beware of is that of irresponsible scribes with more sail than ballast.

The Hatlessness of Womankind.

IN the earlier days of the fashion for hatlessness that recently overcame a small section of our womankind a country vicar banned the practice from his pulpit, and forbade any women to attend his church without a hat. His gospel has been adopted by the Vicar of Clewer St. Stephens, who recently announced his opinion that it was a disgraceful and abominable practice for women to appear in public without their hats. "Was it comely, he asked, for them to appear hatless in the public streets, or did it look modest? Did it not rather look bold and brazen?" Has the worthy vicar, we wonder, analysed the situation? Surely it is no worse for a woman to sit in church with her head bare than it is for a man. Infinitely better, moreover, that she should be hatless than clad in the average extravagant, gorgeous, and often inappropriate and inartistic millinery of to-day, possibly not paid for, to boot. In the theatre mankind with one accord condemns the selfish, vulgar, and stage-eclipsing feminine hat. Why should that which is rejected in the playhouse be sanctified in the church? From a scientific point of view most medical authorities would probably give their unhesitating support to the hatless-ones so lustily abhorred by the Vicar of Clewer St. Stephens. But let him take heart of grace, the feminine hat is far too gorgeous and important an article of dress to be abandoned for any length of time, especially before large congregations of one's fellow creatures.

"Minor Doctors."

ONE of the drug trade journals has been enlivening the "silly season" by advocating the establishment of a new order of practitioners under the above title. Basing its remarks on the fact that at the present time a considerable amount of medical practice is done by chemists and other unqualified persons, our contemporary suggests that these free lances should be given a legal status as practitioners for the relief of minor ailments. It is suggested that the standing of "minor doctor," doubtless with the title of M.D., should be attainable by passing an examination after a curriculum comprising one year of hospital practice and another of "minor medicine and surgery." We presume that the latter terms mean the sort of medicine and surgery that may be practised without any knowledge of the patient's condition, since it is suggested that "to visit patients must be penal," whether to the patient or to the "minor doctor" we are left to guess. Some such idea as this is said to have been foreshadowed years ago by Sir Benjamin Richardson, who suggested it as a mode of relief for the overcrowding of the profession. It is quite possible that the present standard required for qualification as a medical man is too high; it is certain that it could be improved without making it more severe. But the establishment of an inferior order of practitioner is not the way out of the difficulty.

Army Medical Reform and Enteric Fever.

THE breakdown of the Army Medical Department in South Africa showed us where a good many of the defects lay. On the other hand the absolute success of the Japanese in the medical administration of their recent campaign proved what is possible to scientific organisation. British

troops were decimated with enteric fever in one continent, while Japanese armies escaped scot-free in another. The fact of the matter seems to be that the British Army officer wants a complete education in practical hygiene. If Mr. Haldane be in earnest about Army reform, and intends to take the medical bull by the horns, let him first consider the question of camp hygiene. Enteric fever is never absent from our great military depots. Let the Army surgeons go down in batches and investigate, and let prizes and seniority be influenced by results. At present Fleetwood militia camp is being visited by an outbreak amongst the officers. The cause is still obscure, but it affords a fine field for exercising the faculties of budding Army surgeons. The minute investigation of a particular outbreak is worth a years' instruction in the class room. We believe the outbreak at Salisbury Plain depot some years ago was never satisfactorily accounted for. Yet we complain that our Army medical officers are unable to cope with the best understood and most preventable of all water-borne diseases in the field. As to India barracks and cantonments they are riddled with ever-present enteric fever, to the standing disgrace of our Army administration.

Old Highland Whiskey Again.

As might have been foreseen the Islington Borough Council does not intend to let the whiskey question drop. Not long ago their Inspector obtained a summons against a dealer for selling as "Old Highland Scotch Whiskey" an article found to contain 90 per cent. of patent (or silent or neutral) spirit, and 10 per cent. of pot still whiskey. The summons was dismissed on a technical ground, and on the inspector trying to a get a second sample he was served with a bottle having the label, "This is sold as a mixture of patent and pot still whiskey." He has now applied for a summons under the Merchandise Marks Act for selling the original sample with a misdescription. Clearly, consumers are entitled to have what they pay for, whether bought from a grocer or a publican, or any other tradesman. The gratitude of the community is due to the Islington Council for their public-spirited attitude in this matter.

Exfoliative Dermatitis in a Workhouse.

An epidemic of a serious skin affection has been reported from the Sulcoates Workhouse, Hull. Towards the end of last week some 80 patients were isolated, but the disease is still spreading. Some of those affected are said to be in a serious condition, and the matter has been reported to the Local Government Board. There can be little doubt from the scanty reports so far available that the epidemic is one of exfoliative dermatitis of the kind brought into prominence some years ago by the clinical observations of Dr. T. D. Savill. The etiology of the affection has never been absolutely demonstrated, but it appears reasonable to assume that the dermatitis is of toxic origin, and that either toxint or pathogenic organisms are conveyed by some agency common to the infected community, in most instances probably or possibly, milk. It has been further pertinently suggested that the desquamation which is so highly characteristic of the malady is the direct result of excretory damage or irritation to the skin, in the attempt to throw off some injurious product from the circulation. It is to be hoped that Dr. Savill will have an opportunity of investigating the Sulcoates outbreak.

PERSONAL.

His Majesty the King has conferred the decoration of the Royal Red Cross on Miss R. A. Betty, Senior Lady Superintendent of Queen Alexandra's Military Nursing Service for India, in recognition of her special devotion and competency during her long service in the Nursing Service in India.

Dr. Frances Harper, of London, has been appointed lady assistant medical officer at St. Helens. She is to educate midwives, teach women at mothers' meetings and give instruction in day schools and to women teachers.

Dr. Francis B. Rutter has been appointed a Country Magistrate for Wiltshire.

According to the will of Professor Tarnowski, the Russian dermatologist, his estate is to be devoted to establishing a hospital for invalid doctors.

Dr. John Hutchinson, of Claybrook, has received the grant for successful vaccination for the twelfth time.

Lieut.-Col. R. W. Ford, D.S.O., Deputy Surgeon of the Royal Hospital, Chelsea, has been selected for service at Gibraltar about the end of next month.

Major A. R. Aldridge has been appointed sanitary officer, Indian Army Headquarters.

On August 23rd King Leopold received Sir Alfred Jones and the representatives of the Liverpool School of Tropical Medicine, and expressed his gratification at the results achieved in combating sleeping sickness. His Majesty afterwards decorated Professors Boyce, Rice, and Todd.

Lieut.-Col. Coutts has vacated the appointment of Staff Officer to the Principal Medical Officer, Southern Command, and Lieut.-Col. R. W. Ford, D.S.O., has joined the London District for duty.

Major J. Thomson has assumed medical charge of Military Families Hospital at Woolwich, vice Lieut.-Col. R. J. C. Cottell.

A new London ambulance service has just been inaugurated, and will probably be in working order within the next few months. There will be two central stations, Bishopsgate Street and St. Bartholomew's Hospital, where the ambulances will be housed; and there will be nearly 50 sub-stations, similar to the existing fire alarms. The Post Office has received the order to instal them and to fix the necessary wires to connect them with headquarters. Two electric motor ambulances will probably be used, but only one has so far been ordered. It is to cost between £500 and £600. The Ambulance Committee, however, does not quite approve of the electric ambulance, as certain street corners in the City are difficult to turn.

A woman at Desborough, Northamptonshire, has died from spotted fever, a doctor having certified the cause of death.

A CLINICAL LECTURE
ON
THE DIAGNOSIS AND TREATMENT OF RINGWORM.

By G. NORMAN MEACHEN, M.D., B.S.Lond., M.R.C.P.Lond and Ed.
Physician for Skin Diseases, Tottenham Hospital, N.; Assistant in the Skin Department, West London Hospital.

Of all the common skin disorders which we are called upon to treat, few, perhaps, are so irksome or interfere so much with school or domestic arrangements as common ringworm, especially when this affects the scalp. Some idea of its prevalence may be gathered from the fact that out of 1,695 new cases admitted to the skin department of the Tottenham Hospital in 1905, ringworm was responsible for 201. Of these the scalp was affected in 174; the remaining 27 presented the disease in various other parts of the body. The youngest patient was one month old and the oldest 48 years; both these were cases of ringworm of the body (Tinea circinata). Ringworm of the scalp (Tinea tonsurans) is very rare in the adult; I myself have only seen one case. Aldersmith, with his extensive experience, has seen but six cases in twenty years.

Clinically, we may speak of five main varieties of the disease:—

1. Tinea tonsurans, or scalp ringworm.
2. Tinea circinata, or body ringworm.
3. Tinea barbæ, or ringworm of the beard.
4. The so-called eczema marginatum.
5. Onychomycosis, or ringworm of the nails.

1. Ringworm of the scalp, formerly known as Porrigo scutulata (Willan and Bateman), or "scalled head," is not altogether a happy phrase, for it is not at all necessary for the lesion to be circular in shape. Many years ago Dr. Robert E. Brown attempted to show that the growth and progress of the disease was analogous to that of the "fairy rings" of darker grass seen in meadows. It was thought that those cutaneous fungi which we now know to be the cause of ringworm resembled certain creeping plants which extend themselves beneath the soil in both lateral and radial directions. Many cases, however, exhibit no trace whatever of any ring formation, and it is then that difficulties of diagnosis are apt to arise. Like most morbid conditions, its first appearances may be completely overlooked, the child being thought by its parents to be suffering merely from a little scurfiness. Not until a definite bald patch is observed is any serious attention given to the head. The longer it is left to go untreated the more difficult is it to eradicate. The most obvious thing about the typical ringworm patch is the presence of the characteristic "stumpy" hairs. If these be really seen, either with the naked eye or with the aid of a magnifying lens, there can be no doubt whatever about the diagnosis. The diseased hairs themselves are worthy of a careful study. On minute inspection they are seen to be bent in all directions, some being inclined one way and some another. They are nearly always thickened at their point of emergence from the scalp, while their free extremities may end abruptly or may taper off to a point. The general appearance of the stumps has been well likened to "stubble in a cornfield" or to "bent fingers." Sometimes they look as if they had been nibbled by a mouse. They may be very numerous, or, on the other hand, only one or two may be found after much prolonged searching. The base of the patch is nearly always somewhat scaly, and it feels rough to the touch.

Since the discovery in 1843 of the tricophyton fungus by Grüby and Malmsten, and their further elaboration by Sabouraud and Rosenbach (1892-4), we have had at our disposal an absolutely scientific method of detecting the presence of tinea of the scalp, or, indeed, of any other part of the body. There are two main types of fungus (1) the *Microsporon Audouini*, or the small-spored variety; (2) the *Tricophyton megalosporon*, or the large-spored species, *endothrix* or *ectothrix*, according as the fungus lies inside or outside the hair. Small-spored ringworm forms at least 90 per cent, of all the cases of tinea tonsurans seen in this country. The geographical distribution of the two varieties is somewhat peculiar, for the microsporon is only responsible for 60 to 70 per cent. of ringworm cases in Paris, while in Italy it is practically unknown. The arrangement of the mycelium and spores as seen under the microscope also differs in the two species, that of the small-spored fungus being in the form of a mosaic which forms a sort of sheath upon and around the hair-shaft, that of the large-spored being in more or less regular chains or rows parallel with the hair. Cultures of the two fungi upon maltose-agar show characteristic differences, and in doubtful cases may assist the diagnosis materially. If there be the slightest uncertainty the microscope should always be employed, the rapid or potash method of examination being quite sufficient in the vast majority of cases for arriving at a correct decision. For this purpose two or three stumps or suspicious-looking hairs are epilated with forceps, mounted in a drop of the B P. liquor potassæ, and examined with a one-sixth objective. After a few minutes' interval the specimen will have "cleared" and the mycelial network and spores can then be made out. It is important not to confound the spores with minute droplets of fat separated by the alkali. If it be desired to make a permanent specimen the hairs can be stained with aniline-gentian-violet by Gram's method, time being given for complete decolorisation of the hair.

The plan of mopping the ringworm patch with a little chloroform is sometimes a useful one for rendering the diseased hairs more prominent, for after the evaporation of the chloroform the stumps assume a "mealy whiteness," as Allan Jamieson says. Even after considerable experience it is not always easy to be certain that a suspicious area upon the scalp is due to tinea. There are so many pitfalls into which the unwary may slip.

In the first place scaliness may be present to such a marked degree that the case is liable to be mistaken for a simple pityriasis or a seborrhœa capitis. This condition is seldom found in patches

but is generally diffused all over the scalp. The stumps may be very few and far between. In such a case, the best plan is to take a surface scraping of the scaly area and examine this in potash under the microscope for mycelium.

If there be much crusting, as in neglected cases, the condition may easily pass for a simple impetigo, but it should be remembered that under the most innocent-looking crust may lurk one or two hairs affected with tinea. It is, of course, possible for impetigo contagiosa to exist side by side with ringworm or to be engrafted thereupon. The sensation of touch is most useful in scalp affections, for there is a special roughness of the ringworm patch which can easily be appreciated by the sensitive finger-tips, quite unlike the peculiar "rocky feel" met with in ordinary impetigo. If crusting prevails upon one part of the scalp and the case is really one of tinea, it is more than probable that other areas near by will not be crusted over and, therefore, able to be felt by this means. I need hardly emphasise the importance of carefully examining the entire scalp, both with the fingers and with the hand-lens. I well remember seeing a little girl with what I thought was typical impetigo at the back of the neck associated, as is usually the case in this part of the body, with pediculosis. Being rather hurried at the time I was about to dismiss the case when I asked the child to take off her hat. I then saw upon the vertex of the scalp a large patch of ringworm which was not mentioned by her mother!

Inflammatory reaction may be the most conspicuous clinical feature, the diseased area being raised, reddened, boggy, fluctuating, and, perhaps, exuding pus from numerous small openings. This condition is known as kerion. Occasionally, this state of affairs manifests itself spontaneously, but more frequently it is the result of over stimulation of the patch, as with an ointment that is too strong. I have previously reported (*a*) a most instructive case in which kerion was found beneath an impetigo after a week's interval. The child was æt. 11, and on a first examination I failed to find any trace of fungus. At the next visit my search was successful, the *megalosporon endothrix* being found. If ever there was a case resembling impetigo, this was one.

Again, the patch may have such a smooth base as to simulate alopecia areata. The characteristic stumps are not seen and scaliness is absent. This condition, known as tinea decalvans, or "black-dot" ringworm (Aldersmith), or "bald" ringworm (Liveing), is associated with the large-spored fungus. On close inspection, the smooth area presents here and there small black dots, which are the tops of the hairs showing at the mouths of their follicles. These are with difficulty extracted by the ordinary epilation forceps, but may be obtained by using a comedo extractor. In ordinary alopecia areata we should not see these black dots, but instead the peculiar club-shaped or "point-of-exclamation" hairs which are never found in tinea tonsurans. It is important not to mistake the one for the other as the prognosis and treatment are essentially different.

2. Tinea circinata, or ringworm of non-hairy parts, nearly always presents itself in the form of small, well-defined patches in which involution has taken place at the centre. They are very common on the face and forehead of school-children, who are promptly sent home by their alarmed teacher. It often happens, however, that the so-called "ringworm" turns out to be nothing more than a simple patch of squamous eczema. I have previously shown here a little boy who came to the hospital with the story that he was "covered with ringworms," but on examination the lesions were seen to be those of eczema. The mother had fondly smeared them over with ink in the hope of curing the supposed ringworm quickly. The only satisfactory method of diagnosis is the examination of a surface scraping mounted in potash solution. The characteristic branching and jointed threads of mycelium will be found if the case is one of tinea circinata.

When the lesions are very small and scattered about the trunk some confusion is apt to arise with pityriasis rosea. Most British dermatologists have failed to find any trace of fungus in the latter disease, and consider it to be a separate morbid entity, though the Vienna school has long held the view that it is due to a fungus. A unique case was shown by Dr. Graham Little before a recent meeting of the Dermatological Society of Great Britain and Ireland, (*a*) in which pityriasis rosea was combined with tinea circinata in a boy æt. 10, the two diseases existing side by side.

It would not be supposed that tertiary syphilis could be mistaken for this variety of tinea or *vice versâ*, but I exhibited a case before the same Society (*b*) of a woman, æt. 35, who was transferred to me from the eye department of this hospital by my colleague, Mr. R. Philip Brooks, for an eruption of the face and lip, the eyelids also being affected, From the right external canthus there extended a trident-shaped, reddened elevation, accompanied with blepharitis. She also had a patch of similar appearance, circinate and slightly scaly, on the left side of the upper lip. This latter patch strongly suggested a tertiary syphilitic eruption. However, surface-scrapings revealed the presence of a tricophyton with a very fine branching mycelium. The condition had lasted for nearly three weeks. Sometimes the lesions, especially upon the lips, are quite pustular in character, suggesting at first sight a patch of eczema. Itching is much more severe, as a rule, than in the latter affection, and the fungus can be obtained in the surface-scrapings.

3. Tinea barbæ, or hyphogenic sycosis, is a common enough affection of the beard and moustache region, especially when the minor operation of shaving is not conducted upon strictly antiseptic principles. It has recently produced a little flutter of excitement in the law-courts, but it should be remembered that the barber's implements are not always at fault. The common grey coccus which inhabits the upper layers of the epidermis has been proved to be capable, under certain circumstances, of taking on a virulent form, so that it is quite possible for a patient to become infected from his own skin through a minute abrasion inflicted by a perfectly sterile razor.

Hyphogenic sycosis may generally be distinguished from the coccigenic variety by having fewer, if any, pustular lesions and by being more lumpy, swollen and infiltrated. The hairs may be pulled out easily and the fungus can be seen microscopically. Syphilis, that "rare imitator," may occasionally simulate ringworm of the beard.

(*a*) MEDICAL PRESS AND CIRCULAR, 1903 ii., p. 194.

(*a*) *Brit. Journ. Derm.*, vol xviii., p 184.
(*b*) *Ibid.*, vol. xvii, p. 185.

I have described the case of a coachman, æt. 50 (*c*), who complained of a sore lip, and in whom there was every appearance, clinically, of a lumpy sycosis. No fungus could be found on examination, and he had, in addition, an infiltrated patch on the arm, which, of course, cleared up the diagnosis.

4. The so-called "eczema marginatum" is only a clinical appellation for that variety of ringworm attacking the groins and axillæ. It is identical with the Dhobie itch of the tropics. When found in the perineal region it more commonly spreads downwards on to the thighs and very rarely mounts upwards to the abdomen. Owing to the heat and moisture of the affected parts it seems to be much more resistent to treatment than tinea circinata; it is certainly more common in private than in hospital practice. The margins are always abrupt, the general tint of the lesion is rather darker, as a rule, than is seen in tinea circinata, and the irritation is intense. It resembles somewhat a seborrhœic eczema, but the patch does not weep, and mycelium can be found in the surface-scrapings.

5. Ringworm affecting the nails only, or onychomycosis, is not very common, but it is very troublesome. The finger-nails are usually attacked, and they gradually become brittle and of a greyish-yellow tint. When the whole nail-plate is involved the free edge may show an accumulation of epithelial *débris*. The diagnosis is rendered complete by examining scrapings from the nail in potash, but the fungus is sometimes very difficult to find. Without the microscope it is almost impossible to distinguish this condition from psoriasis of the nails.

The question of treatment may be prefaced by saying that accurate diagnosis is absolutely essential, and that ringworm of the body is much more easily cured than that of the hairy scalp.

It was a favourite dictum of Tilbury Fox that too much attention is paid to the mere surface changes in the treatment of tinea tonsurans. The older dermatologists were greatly impressed with the necessity of giving internal medicine at the same time, and this is not surprising when we recollect that the fungus was not discovered until 1843. Knowing, as we now do, the life-history of the microsporon and the tricophyton our aim in treatment is to get rid of the fungus as quickly as possible. This can only be accomplished in two ways—(1) by the use of such anti-parasitic remedies which will penetrate easily into the hair-follicles and so destroy the fungus *in situ*, (2) by causing a rapid falling of the diseased hairs, so that when these are shed the fungus comes away with them. Up till quite recently, the first method was the only one commonly employed. The great difficulty has been to find a substance with sufficient penetrative powers that shall not prove too destructive, and I regret to say that we do not yet know of such an agent. If the cases of tinea tonsurans are seen early enough almost any germicide will be effectual. The popular use of ink is at least sanctioned by ancient authority, but it should be remembered that the "atramentum scriptorum" was a carbonaceous product and not a gallate of iron, as in modern times. From ink to gunpowder, the number of parasiticides which have been used is legion. Whichever one happens to be our favourite, whether it be carbolic acid, sulphur, chrysarobin, or mercury, let it be used thoroughly. Over-activity, however, is as disastrous as insufficient treatment is useless. It is very easy to produce an artificial kerion by the vigorous application of some strong preparation, and this may lead on to a condition of permanent alopecia—a most undesirable event. Such formidable remedies as formalin, pure carbolic acid, or croton oil need especial care in their application and should never be entrusted to parents themselves. There are certain general rules for the management of a ringworm case which it is essential to observe in order to obtain the best results:—(*a*) The whole scalp should be shaved when possible, particularly in boys, while a thin fringe may be left in front for the sake of appearance in the case of little girls; (*b*) the head should be kept covered with the ointment selected and a thin cap of old linen should be worn both by day and night. Soft paper is not a bad substitute for linen, if expense is a consideration; (*c*) too frequent washing of the scalp must be avoided; (*d*) epilation should be practised in and around the diseased areas as often as possible. I am in the habit of giving printed instructions for the management of ringworm to the parents who bring their children to the skin department at this hospital, based upon the above rules. I will now only mention a few of the many methods employed for the destruction of the fungus *in situ*. The application of an ointment containing β-napthol, sulphur, and vaseline; of tar and sulphur (the old "Wilkinson's ointment"); of Coster's paste, a mixture of iodine and tar; painting the area with salicylic acid collodion (Crocker); blistering with tincture of cantharides (Hallopeau). Equal parts of pure carbolic and salicylic acids (½ dr.-1 dr. of each to the ounce of vaseline or lanoline) make a useful ointment. If the case is able to be seen frequently, chrysarobin can be added cautiously to this latter ointment for application to the diseased patches only. The plan adopted by Abraham, of exhausting the air from the follicles by means of a special hand-pump and then running in creosote and iodine, is a most excellent one, and I have seen many cases of ringworm cured by this means.

The depilation method, as practised by Aldersmith, has also been successful, though it is not so easy to apply and carry out. By sopping the area with a saturated solution of boric acid in spirit and ether an artificial alopecia is induced, after which the new hair grows regularly and is found to be free from disease. In 1883 Aldersmith prophesied that an easier way of producing an artificial alopecia areata in the affected areas would be found, and now to-day we have the X-rays coming to our aid in the treatment of this most troublesome disease. Suggested by Freund, of Vienna, in 1896, it is only by the researches of that distinguished French dermatologist Sabouraud that the method has been rendered anything like practicable. The hair begins to fall out about a fortnight or so after exposure of the scalp to the rays, and the defluvium is complete in a week. In six weeks' time healthy hairs start growing again and in three months the disease is cured. This method has been employed in the treatment of ringworm in the Municipal Schools of Paris, and the saving of time and expense and loss of education has been very great indeed. It should not be forgotten, however, that the treatment is not altogether without its risks and attendant dangers, but there can be no doubt that in skilled hands it has proved and is

(*c*) MED. PRESS AND CIRC., 1903, i., p. 89.

proving a most valuable addition to our therapeutic armament.

When is ringworm cured? It is almost impossible to lay down a definite time-limit, as there are so many factors at work. In ordinary cases, if the hearty co-operation of the parents can be obtained, about four or five months is a fair average, though it must be admitted that many cases do go on for even years, in spite of all treatment. The point is "How does the hair grow?" If the growth is absolutely uniform, and the direction of the hairs is natural and even, then that patch is cured. It is generally wise to make a microscopic examination of any hair that looks at all suspicious before deciding whether a child is fit or not to go back to school. If no spores are discovered, the disease can be pronounced cured, but it is a good thing to advise that a little of the ointment be still rubbed in at night-time for another fortnight.

The application of a cap-film, such as that suggested by David Walsh, is a valuable means of preventing the infection of ringworm of the scalp spreading to other children. After shaving, the whole scalp is covered with a film of salicylic acid collodion, after exposing the diseased part to the X-rays, and the child can then attend school with perfect safety. This "scalp-isolation" is also indirectly curative, as it hastens the depilation of the hairs.

Ringworm of the body can soon be cured by painting with tincture of iodine or by the application of a mild ammoniated mercury ointment. In cases of tinea barbæ, depilation should be practised as far as possible, and the hairs clipped quite short. An antiseptic fluid such as cyllin, suitably diluted with warm water, is useful for bathing the affected parts, after which an ointment containing carbolic acid, sulphur or ammoniated mercury can be applied.

For ringworm of the nails, the plan of treatment devised by Harrison, of Bristol, is one of the best. It consists in scraping the nail well and immediately applying a solution of potash and iodide of potassium under oiled silk for a quarter of an hour. This is then taken off and a solution of perchloride of mercury, 4 grains, in equal parts of rectified spirit and water, up to ½ oz. is next applied and kept on for twenty-four hours. This is repeated as often as necessary.

Vaccine Laboratory.—The Government's new vaccine laboratory which is being built on the Collindale estate, Hendon, is expected to be opened shortly. The site covers more than two acres, and a sum of about £20,000 is being expended. The buildings, which will include operating room, heating station, and the necessary stable accommodation, are within a short distance of the British Museum's storehouse for newspapers.

ORIGINAL PAPERS.

TWO CASES OF RESECTION OF INTESTINE FOR MALIGNANT DISEASE.

By G. P. NEWBOLT, M.B., F.R.C.S.,
Surgeon Royal Southern Hospital, Liverpool.

Case I.—*Excision of the Cæcum for Colloid Carcinoma.*

Edwin G., æt. 38, a pawnbroker, was brought to me in April, 1904, complaining of a lump in the right ilio-lumbar region, which was giving rise to a good deal of pain.

His previous history was that he had had pain in the right side of the abdomen for twelve months, and had lost 16 lbs. in weight during this time. For the last three months the pain had been much worse, and a lump had been noticed in the right side. Four months ago he had an attack of diarrhœa and was jaundiced. At that time his liver was enlarged. Had always partaken of stimulants freely.

On examination, a tumour about the size of an orange could be felt in the right ilio-lumbar region. It was hard and tender, and could be pushed into the loin. At first it was thought that it might be a kidney growth, but the normal condition of the urine and the fact that the tumour was situated too far forwards and downwards rather negatived that idea. There was a band of resonance between the tumour and the liver which excluded disease of the gall-bladder, though the liver itself was slightly enlarged. There was at this time no constipation nor sickness. Patient was admitted to the Royal Southern Hospital on April 21st, 1904.

Here a careful examination and measurement of the urine passed excluded kidney disease, and the resemblance of the case to one of cancer of the cæcum which I had recently had under my care induced me to think that I was dealing with a growth of this part of the intestine.

On April 26th, the patient being under ether, I made an oblique incision extending from the right loin over the tumour nearly to the middle line below the umbilicus. On opening the abdomen a big growth involving the cæcum was found, and it was thought possible to remove it.

After having packed the intestines off with gauze, the ilium was exposed, clamped in two places and divided between, a little mucus being caught on gauze dabs, and the severed ends of the intestine and the clamps wrapped around with gauze.

The ascending colon was next isolated and treated in the same way, some adherent omentum being ligatured and cut away. The peritoneum external to the tumour was next dissected up from the loin and iliac fossa and the growth separated, except on its inner side. A V-shaped piece of mesocolon containing some enlarged glands was exsected and the mass removed. Many large vessels were tied, gauze used to pack off the wound, and the two ends of the divided gut brought together and united with silk. As the small intestine did not fit the large, a piece of the latter was puckered up and sewn over; finally the line of union was secured by Lembert's sutures all around, and some omentum used to cover in the joined parts. The edges of the V-shaped cut in the mesocolon and mesentery were carefully sutured. The wound being quite dry, all gauze was removed and the wound was closed completely.

Patient's condition after the operation was excellent. On the second day his temperature rose to 102° and he had a bronchitic attack, which speedily subsided. The wound healed rapidly, but had to be opened at one spot on the 14th day to let out some pus, and from this opening several bits of silk came away, but there never was any fæcal discharge. His bowels acted slightly on the 2nd day after operation, and again on the 5th day, when

a formed motion was passed. Six days after operation he was taking fluid nourishment freely. A month after operation had had a severe bilious attack, which however soon subsided.

His present condition is good; he feels well and has put on flesh lately, though his weight now is less than it was when he went into hospital, 9 st. 2 against 10 st. 8½.

I fancy his liver is slightly enlarged (Nov. 1904). The growth is a colloid carcinoma, involving the cæcum, but not causing any constriction of the lumen of the gut. From the size and nature of the growth, together with the fact that glands were enlarged, of course the prognosis is doubtful (fig. 1).

April 1905.—Patient continues in good health and has put on weight.

[*Note.*—June 1905.—Has secondary deposit in liver, and is rapidly wasting.

CASE II.—*A Case of Left Inguinal Colotomy for Intestinal Obstruction, followed by simultaneous Excision of the Growth, and artificial anus.*

On May 20th, 1904, I saw Mrs. H., æt. 53, suffering from intestinal obstruction.

Her history was as follows:—She had always enjoyed perfect health until the end of March, 1904. On April 2nd she called her doctor in for what she thought was a bilious attack. Purgatives acted freely, and nothing could be made out by external examination. As she did not improve and her abdomen began to extend, I was asked to see her.

On examination, her abdomen was much distended, especially in the flanks, and nothing in the nature of a lump could be felt externally or per vaginam or rectum. There was a distinct history of her passing ribbon-like fæces, and her mother died of cancer of the stomach. She had had ten children, the youngest being eleven, but there was no history of any pelvic inflammatory trouble.

On May 24th I did a left inguinal colotomy. The obstruction had now become acute, and I drained the bowel at once with a Paul's tube. In passing a pair of forceps under the distended gut in order to keep it out of the abdomen whilst I stitched it, the gut was accidentally perforated in two places; these I clamped off and closed, after I had sutured the gut to the edges of the wound and had drained the bowel.

At the end of August she came to see me, being anxious to have her colotomy wound closed if possible, her medical man having felt the growth through the upper opening of the colotomy wound.

On examination, I found that the lower opening was the artificial anus, or, in other words, that the bowel was twisted, and down the upper or distal opening a growth could be felt which was freely movable and some 2 inches from the artificial

anus. I therefore determined to excise the growth and leave the artificial anus for a time, but this did not suit the patient, who could not be brought to appreciate the benefit of her artificial anus, and wished to be cured at one operation.

I may say the artificial anus was acting well, and the skin around was in good condition.

On September 1st, after several careful preparations of the skin around the artificial anus, the latter was plugged with gauze, ether administered, and an incision made on the inside of the opening, a flap of abdominal wall was reflected and tied down over the artificial anus with sutures. The growth was found, clamped above and below, and excised with a piece of mesocolon; the gut leading to the lower or real opening was next clamped and divided between, and all bleeding having been stopped, end-to-end suture was performed. This was difficult on account of the contracted state of the distal end of the gut. The union was strengthened by being covered with a piece of omentum; some mesocolon containing glands wa next excised, and the edges of the opening closed with sutures. The colotomy opening was next excised, the inner abdominal wound closed, and the one in the site of the artificial anus partly closed and packed with gauze. Patient left the table with a pulse of 100.

Next day patient was very ill and suffered great distress from the fact that flatus was collecting behind the line of union, she vomited, her abdomen became a little distended, and her pulse ran up to 160; however, at 5.30 p.m. on the second day, flatus passed and her bowels acted slightly; after this her bowels acted regularly without an aperient, and she improved so rapidly that on September 29th, a month after operation, she was able to return home, and a letter which I received a few days ago said that she was quite well, got about as usual, and could eat anything.

The growth is an ordinary adeno-carcinoma of the bowel, and allows a quill to pass through the lumen; the glands in the mesocolon are enlarged.

The points of interest are:—

(i) The reversal of the colotomy opening, due to a half twist of the bowel, or to a very marked sigmoid curve.

(ii) The great objection to the colotomy wound by a strong healthy woman, although it acted well and the skin around was not irritated.

(iii) Whether it would not have been safer to have first removed the growth, bringing the distal end of the gut into the colotomy wound, and cutting away the spur later on.

My own experience of cutting away spurs is that it is a very tedious process.

"QUO VADIS?"

A PLEA FOR MORE COMMON SENSE IN THE PROPHYLAXIS AND TREATMENT OF DISEASE.

By CHARLES BELL TAYLOR, M.D., F.R.C.S.Ed.

Hon. Surgeon to the Nottingham and Midland Eye Infirmary.

MR. PRESIDENT AND GENTLEMEN,—When Molière, the great French dramatist, satirised the members of our learned profession, he declared that the whole art and science of medicine might be summed up in three words, "Purgare, Saignare, Glysterium donare," and if anything further was required it was simply—"Re-purgare, re-saignare, glysterium re-donare."

Voltaire, Le Sage, Hugo, and other eminent Continental writers have similarly criticised us, and that we do not lack a like sense of humour on this side of the Channel is evidenced by the popularity of that well-known skit upon the late Dr. Lettsom—

"When folks are sick they send for me,
I physicks, bleeds and sweats 'em,
Sometimes they live, sometimes they die,
What's that to me, I Lettsom."

Of course we laugh, Englishmen are always good-natured enough to laugh at themselves, but, after all, what is there to laugh at? I protest that the treatment, though Molière meant to be sarcastic, is rational enough; indeed, if he had added to his epitome of the art and science which we all profess, "Sudare, et blisterium imponere," it would have been to my thinking well-nigh complete. What, for instance, could be more in accord with the principles of common sense when called to a case of acute or chronic or threatened disease than to clear out the primæ viæ, to wash out the stomach with tube or emetic, to rid the colon of accumulated hardened or pestiferous fæces, to cleanse the skin with suitable baths, and to start the treatment with what Lord Rosebery would term a clean slate. Again, when we have to deal with congestion, inflammation, cell exudation and immigration, leucoccytal disturbances and the like, when we have robor, tumor, calor, dolor, throbbing, shooting, burning, what can be more reasonable than to cut off the supplies. to stop the beginning before it begins, to drain the gorged vessels and ease the raging pain by the abstraction of blood? We all know that tissue reaction to irritants with hypercellularity will cause almost any disease, carcinoma, for instance. Simple scratching will cause epithelioma, and the irritation of gall-stones cancer of the liver, while mere compression of an artery that supplies a painful part will stop the process and cure the neuralgia.

Compression of both carotids will cause instant insensibility, hence the term from "Karos," sleep. I have seen a patient, worn out from loss of rest and agonised with the stabbing pain of acute pleurisy, instantly relieved turn over and go to sleep as the blood flowed from a wound at the bend of the elbow Syme, the Napoleon of surgery, used to say, "If there is pain, take a few ounces of blood from the arm." Von Grafe said precisely the same thing if there was pain after cataract extraction. Alison, the late eminent professor of the practice of physic in the University of Edinburgh, used to tell us that "Forty years' experience had taught him the great value of blood-letting in the treatment of disease." I have seen horses with their eyes protruding, their nostrils dilated, their limbs fixed, and gasping for breath, relax, heave a deep sigh of relief and commence to feed as the blood gushed from a free incision in the jugular vein. I have known a woman afflicted with delusions murder two of her children, and then cut her own throat. As the blood flowed from the superficial self-inflicted wound the cloud was lifted, the written troubles of the brain were razed out, the eyes of her mind were opened, and with infinite horror she realised what she had done.

A friend of mine who incised the median vein with a razor has seen the same instant relief followed by complete recovery in a case of puerperal eclampsia. I have known and recorded cases of stalwart men, who were, humanly speaking, lost in their prime solely for want of bleeding. Whence this neglect, this dread of a simple operation which our predecessors practised almost every day of their lives? We have only to look at their diaries, day-books, and ledgers to find in the constant recurrence of "iter venesectio" ample confirmation of this statement. Are we so much wiser than our fathers? I doubt it! We have each about fifteen ounces of blood for every stone of weight, ten

(a) An address delivered before the Nottingham Medico-Chirurgical Society on November 15th, 1905.

ounces abstracted to-day is replaced by new and presumably better material within a fortnight, and there can be no doubt that it is wise to let out and replace with water or saline drinks blood that is effete or too thick to circulate freely, or that is poisoned by gas, opium, foul air, or auto-infection.

Venesection, too, is of infinite value in taking off the pressure from vital parts, which pressure, if unrelieved, as in cases of congestive apoplexy for instance, must end in disaster. If I find that the water does not flow freely in my bath-room, I know that they are running it off in the kitchen, and if I open a vein in the arm I interrupt, stop, arrest, or slow the hæmorrhage which is taking place elsewhere and which might prove fatal. Think of what this means when a patient is bleeding to death from the nostrils or lungs or intestines, who is threatened with cerebral hæmorrhage, who staggers in the street, or, breathing stertorously, falls convulsed upon the floor. Some years ago I operated on a patient for another affection who had long suffered from repeated attacks of epistaxis. After a somewhat prolonged exemption from his usual loss he was suddenly seized with violent pain in the head; he felt instinctively that he ought to be bled, and applied to three medical men in succession, begging each to open a vein. They all refused. "We never bleed now," they said. He went home disconsolate, was seized with a fit the same night, and died paralysed shortly afterwards. It is a mistake to suppose that the loss of a little blood, or a lot of blood for that matter, is of any great consequence. I once accidentally wounded an artery in my own person; the hæmorrhage could not be controlled, and I lost a tremendous lot of blood. On another occasion I put on twenty leeches; the bites bled more or less all day, all night, and most of the next day. I did not attempt to stop them, my clothes were saturated, and whenever I took a hot bath the water was literally incarnadined and resembled red ink. I did not on either occasion lay up for a day or interrupt my practice, and felt no worse. They used to bleed very freely in the Army; "pleno Rivo," or a hatful of leeches, or both, was a common prescription. One gallant soldier, an Irishman, bled by the order of Guthrie, said the treatment made him feel "powerful weak, but cruel easy." The men dealt with in this way for supposed malingering were positively drained and looked like ghosts, but I suppose they recovered, since we have no record of untoward events. The President of the Glasgow Medico-Chirurgical Society reports a recent case where two hundred ounces of blood were abstracted with the best results, and Benjamin Rush, a celebrated Quaker, physician of Philadelphia (who was libelled for his practice of bleeding by Cobbett, and recovered five thousand dollars damages), had in his time hundreds of similar cases. We all know what happens in cases of placenta prævia, in some cases of malignant disease, Bright's disease, accidental hæmorrhage and the extraordinary losses which women sometimes suffer in childbed, apparently without much detriment. A medical friend of mine practising in this county, and over eighty years of age, used to take off the pressure, as he termed it, *i.e.*, bleed himself, whenever he felt out of sorts. Both his arms, as I saw, were scarred with repeated venesections. He said the operation had saved his life more than once, and eagerly offered to open a vein in my presence. Why do we neglect so great salvation? The indication is so obvious, the treatment within reasonable limits so harmless, the results so immediate and gratifying that it is impossible to understand why such a valuable therapeutic remedy should have fallen into disrepute and almost complete disuse.

So much for "Saignare"; now as to Molière's "Glysterium donare": I do not think we can over estimate the importance of rectal alimentation in disease. Many patients have owed their lives to high enemata, and it is desirable that we should bear in mind that the colon is something more than a mere receptacle for refuse or effete material; it is really a most important assimilative and digestive organ. Professional starvationists owe their lives to the colon, entombed miners deprived of all sustenance except perhaps a little dirty water, will live for weeks, but not if they have diarrhœa; and by supplying nutriment by way of the colon, we utilise this function to the utmost, and give complete rest to the upper portion of the intestinal canal just as effectually as if we had opened the abdomen and performed gastro-enterostomy, or excised a portion of its contents. Straus mentions a case where a man was exclusively fed in this way for ten weeks, and the blood constituents did not suffer, nor was the power of the heart diminished. Moreover, it is easy to pass nutrient fluids through the ileo-cæcal valve, and when in the small intestine they are digested just as though they had passed through the stomach—indeed extra-buccal treatment, though neglected, is a valuable therapeutic agent, and it is clear that we cannot afford to ignore it, more especially since Professor Bourget, of Lausanne, and more recently Theodore Zannger and others have demonstrated that high enemata constitute the very best treatment for that "maladie à la mode," which we call appendicitis.

Bourget does not hesitate to bleed with leeches or purge his patients with castor oil, but he places his chief reliance on warm injections, rendered antiseptic by hermani ichthyol. These are passed through a long tube so as to reach the affected parts, and he declares that when this is done pain and tension cease as if by magic, that the temperature falls, and that agony is at once replaced by repose, sleep and speedy restoration to health. He also points out that even if pus be formed it may be absorbed or discharged innocuously into the bowel, or come to a head on the surface. Now it is notorious that unoperated cases of appendicitis as a rule do not die, it is also true that the mortality of patients operated on in the acute stage is excessive (at least 20 per cent.), and that the mortality of patients operated on in the quiescent stage is very low. The object of treatment must therefore evidently be to arrest the inflammatory process in the early stage, and to operate, if operation is necessary, when the acute symptoms have passed off, and this is precisely what Bourget does. He has treated upwards of fifty cases in this way; he gives minute details of the most interesting of them, and he assures us that he has had no operations in the acute stage, no accidents, and not a single death—"aucun cas de mort." Some of these cases were operated upon after recovery from the acute stage and exhibited the characteristic lesions of appendicitis, so that there can be no doubt as to the correctness of the diagnosis. He also points out that the removal of the appendix is no guarantee against subsequent attacks, and may even cause them; also that it is only when the parts have become gangrenous, or are approaching that condition, that the operation in the acute stage is necessary or justifiable.

"What say you, gentlemen— shall we operate on this case or not?" The six students and young surgeons who were in attendance at the bedside were of opinion that operation was not advisable. "You are wrong," replied the Professor, "I shall operate at once." "No you won't," exclaimed the patient, who was a betting man; "six to one is good enough odds for me, give me my clothes."

So much for glysterium donare; as to sudare and blisterium imponere we all know that the skin is the largest organ of the body, it is also one of the most important and most easily accessible; we can see its pores open and shut, it gives off several ounces of fluid every day, and it is easy to understand that any check to this natural function, especially in deteriorated constitutions, is apt to prove very serious. In short, common cold and its sequels are said to cause no less than one hundred and twenty thousand deaths in Great Britain every year. Much of this excessive mortality may be prevented and the colds aborted by

judicious management of the skin, hot baths, lamp baths, taken either in or out of bed, with Dover's powder, pilocarpine and quinine or salicylic acid; and quinine will often speedily terminate an attack which, if neglected in the early stages, might have proved fatal. Moreover, the function of the skin may be utilised so as to take off the heat and burden from internal organs. For instance, it will take on the functions of the kidney, and though in a less degree than the mucosa, vicariously eliminate urea; it will also supplement the functions of other internal organs such as the lungs, liver, pancreas, and spleen, whenever these important organs are oppressed or silted up by hard living, actual disease, injudicious diet, too much meat, gout, alcohol or tobacco. Here is a fine field for therapeutic endeavour, a field which has been cultivated by the most eminent hydropathic physicians, from Priestnitz, of Grafenberg, who never wrote a line, and yet attracted the crowned heads of Europe and distinguished patients from all parts of the world, to such well known ρ actitioners as Gully (the father of the late Speaker), Wilson and Edward Johnson, of Malvern, Currie, of Liverpool, and others. These gentlemen made the most of the skin, and by means of lamp baths, Turkish baths, compressed air baths, packs, hot and cold douches, water blisters and other counter-irritants, succeeded in securing excellent results in many cases that had baffled the most accomplished practitioners. We can also, by acting on the skin, independent of hydropathy, distract the attention of the nervous system and thus counteract morbid processes going on in deep-seated and vital organs. For instance, it is said there is no remedy so good for phthisis as the counter irritation of an attack of acute eczema in the shape of small-pox (Sir William Broadbent). The late Professor Syme used to treat cases of morbus coxarius with the actual cautery to the skin over the affected part, and, to use his own words, "the relief was no less speedy than complete." Mr. Pott used to cure paraplegia and ataxy by issues, setons and other counter-irritants placed in the cellular tissue alongside the spine—"one fire burns out another's burning." Shakespeare also tells us, "Take some new poison to thine eye and the rank venom of the old will die," and that is precisely what occurs. Let me illustrate my meaning: when the beetroot sugar industry in Germany was threatened with extinction through the ravages of a parasite called the eel-worm, Professor Kühn saved the situation by planting a worthless weed of which the worms were exceedingly fond alongside the roots; the parasites turned from their dainty dish to feed on garbage, and were cast into the fire; and we can do precisely the same thing in surgery. If a vital or important organ, such as the eye, for instance, is threatened with extinction or serious damage by inflammation, we can save it by bleeding with leeches and establishing another inflammation in a less vital organ, such as the skin near at hand. The attention of the nervous system is withdrawn from the threatened vital organ and expended elsewhere, while the materies morbi are diverted to some other part where they are harmless, and we are masters of the situation. We cannot over-estimate the importance of the nervous system in these cases. When a man suffers from rigor and shock such as sometimes occurs on the introduction of the catheter, and this shock is so serious as to be followed by suppression of urine, he will die from uræmia and acute congestion if you cannot speedily divert the attention of the nervous system from the kidneys to the skin. When a woman is seized with a rigor on the introduction of a foreign body into the uterus (as has happened in cases of criminal abortion), she will die unless you can speedily rouse and distract the attention of the nervous system. The same thing has happened and proved fatal in a case of hysterectomy, although on *post-mortem* examination all the organs were found to be quite healthy. The late Pope Pius IX. suffered from fits whenever an ulcer on his leg was allowed to heal. A child quite recently died in a London hospital from the too rapid healing of an eczema, though she was in other respects as healthy as healthy could be. When a delicate girl suffers from sudden and intense fright she is apt to develop palpitation and protruding eyeballs unless we can speedily distract the attention of the nervous system. When a paraplegic afflicted with hysteria is roused with a cry of fire she has been known to recover the use of her limbs and run downstairs, though she had been supine and helpless for months, or in some cases for years. Quite recently a cripple in London, passing a house on fire and, roused by the cry of a child, threw down his crutches, dashed into the house and rescued the baby. A lady, addicted to play but a bad loser, was one evening most unfortunate at cards; under the influence of the chagrin so occasioned she developed glaucoma and lost the sight of the right eye. Warned by this terrible mishap, she abandoned her favourite pastime for a year and a half, when, being tempted, she again ventured, was again unfortunate, and lost the sight of the remaining eye (Fischer). A distinguished engineer, during the siege of Paris, ascended in a balloon to make observations, was caught in a contrary current, driven into the enemy's lines, and taken prisoner. That same night he was attacked with glaucoma in both eyes (Wecker). A nurse, worn out with watching at the bedside of a dying patient, fell asleep and was suddenly roused by a loud crash—the sash cord had broken; glaucoma came on within an hour in the right eye, and the left was speedily affected in the same way (Lawson). Chorea, as well as glaucoma and Grave's disease before mentioned, epilepsy, paralysis, jaundice, paralysis agitans, blindness and acute mania have been caused by psychic disturbances, to which many persons are subject. We all know of the Indian method of detecting crime by the drying up of the salivary secretion, and the orator's trouble in the same direction, how the back "opens and shuts" on acute excitement, and how toothache vanishes when we knock at the dentist's door. Mock executions have on several occasions proved fatal, and in fact you can accomplish wonders by suggestion, hypnotism, mesmerism, Christian Science, and by acting on the mental and nervous systems of excitable or more or less mentally afflicted sufferers. In fact I have on several occasions restored the sight of patients suffering from hysterical blindness by drawing sparks from the eye.

To sum up, then, let us treat disease on common sense principles by removing the cause, by raising the standard of vital resistance, and by cultivating health.

"Crescit indulgens sibi dirus hydrops
Nec sitim pellit nisi causa morbi
Fugerit venis et aqueosus albo
Corpore languor"— Horace.

Let us realise the importance of attending to the primæ viæ by emetics, laxatives, and derivatives in the early stages of diseased conditions. Let us stop inflammatory processes *ab initio* by judicious depletion. Let us utilise the colon as an assimilative and digestive organ in all diseases requiring rest for the upper portion of the intestinal tract. Let us get at the *fons et origo mali* in cases of typhlitis, perityphilitis, and appendicitis by judicious local depletion, counter-irritation at McBurney's point, opiates and high enemata. Let us recognise the importance of the skin as an absorptive, depurative and vicarious organ. Let us soothe and guide and distract the roused and ofttimes destructive reaction of the nervous system. Let us fully recognise the vast importance of the principle of counter-irritation, and above all, let us do no harm!

When a certain Scotch young lady was told that the late Queen had taken chloroform, she said "she didna ken it had reached so fair sooth as London," and in my humble opinion it is a pity it ever did reach London; it is, in fact, a lethal agent, has caused

thousands of deaths, and no doubt will cause many more, whereas ether is as safe as safe as can be, especially when given by the Joyce-Jeffries or open method; it is excellent for children, quite as rapid as chloroform, and when nebulised, as I have proved, by nitrous oxide, quite as pleasant to take. "Which anæsthetic will you have, gas or chloroform?" "Oh, ether will do." We all know what good medicines will do in certain cases, but I fear we do not always realise what harm may sometimes ensue from their administration. "Did Mrs. Smith take her medicine?" "Yes." "How do you know?" "I saw the blinds were down!" Digitalis is an ideal drug, especially when given in the form of freshly prepared infusion, notably in cases of dropsy. Nevertheless, I have known patients and friends of my own die very suddenly on change of position when taking small doses of the tincture, a much more dangerous preparation. I have known a distinguished physician prescribe a favourite mixture of his in bronchial affections for upwards of thirty years; at last he took it himself—and never ordered it again. Never give bromides to patients over sixty-five years of age, and let us not forget that arsenic in medicinal doses has been reasonably credited with causing cancer. Mercury is one of the most valuable of remedies; it should be given, however, in the form of blue pill in full doses or by inunction. In cases of hard chancre it completely aborts constitutional syphilis (Hutchinson), and so long as the weight of the patient is not diminished it may be continued indefinitely. A mixture containing a small proportion (one-eighth of a grain to the ounce) of biniodide of mercury is a specific for diphtheria (Luff), while intubation is a vast improvement on tracheotomy, which last operation is exceedingly difficult to perform on infants and very small children. Eliminating meat and salt from the dietary is excellent treatment in gout, rheumatism, migraine and allied uric acid affections. It is worth while remembering that people who are taking salicylates do not catch cold, and that a strong solution of salicylate of soda is one of the best gargles for catarrhal sore throat. Tobacco smoking is a fertile cause of amaurosis and other nervous affections, as also of cancer of the lip, tongue and throat. "How is it that you use so much tobacco?" said a wife to her husband. "Because I chews," was the reply. Yes, they chew when they cannot smoke, and some, it appears to me, would rather smoke than see. On the other hand, opium smoking is a valuable therapeutic remedy far too much neglected. Setons at the back of the neck and subconjunctival injections of saline solution dionine (2 centigrammes) is excellent treatment for infiltration and detachment of the retina, as is also the insufflation of powdered dionine into the conjunctival sac. It is a mistake to ascribe everything to syphilis; "omne ignotum pro syphilitico" is, I fear, a justifiable reproach. "There is a typical case of syphilitic teeth," said a physician to his class. "Perhaps you would like to examine them more closely," said the patient, removing the set from his mouth. It is recorded that Sir Benjamin Brodie once ordered some medicine for a patient, and then sent his man full gallop after the messenger, to say that they were to try it on a dog first. I have known a patient take a dose of mixture and instantly fall convulsed and senseless on the floor. The doctor who had ordered the medicine was sent for, and arriving in hot haste, took a dose himself just to show there was no harm in it, and at once fell convulsed and senseless beside his patient (the dispenser had substituted cyanide for bromide of potassium). Precisely the same thing happened in the case of the Duke of Athol, who had five physicians—two declared he was poisoned; one of the two insisted on tasting the contents of the stomach, and was immediately seized with symptoms of acute poisoning himself. Indeed, we cannot be too careful.

Let us realise that in giving expert evidence both sides must be heard if justice is to be done, and this is especially important in the very first stage of the inquiry. If there is a chemical analysis, or a *post mortem* examination, or an examination of the plaintiff's person in cases of alleged outrage or injury, the accused must be represented while there is time to refute or criticise the evidence for the prosecution, and before the accused is committed for trial. If this precaution had been taken in the Mattersea rape case, in the Chesterfield rape case, in the Grimsby starvation case, the innocent persons who were found guilty and subsequently liberated (on my own petition) would not have been convicted. Certainly we may say the same with regard to the expert report on the handwriting in the Adolph Beck case, and perhaps also with regard to the chemical analysis in the Maybrick case, and the examination of blood and horse hair in the Edalji case.

With regard to the prophylaxis of disease considered apart from the treatment of disease. We all know that in ordinary circumstances "prevention is better than cure," but prevention is *not* better than cure when the remedy is worse than the disease. The late Contagious Diseases Acts (Women) was a glaring instance of this, indeed we err if we suppose that we can afford to tamper with plain right and wrong, our own consciences tell us in a moment what is right and what is wrong. "Æquitas ipsa lucet per se, dubitatio cogitationem significat injuriæ," and if we do wrong or induce others to do wrong, or sanction wrong-doing, we may rest assured that we are on the wrong track, that Nemesis awaits us, and that, in short, it is impossible to do wrong and come out right. We may thank God that it is so, for a crime that succeeds is worse than a crime that fails—there is no end to its evil influence. Without doubt, it is wrong to torture animals under pretence of advancing science by vivisection. Nothing can be right that is unjust or cruel, and deliberate cold-blooded and prolonged torture of innocent and unoffending animals is both hideously unjust and atrociously cruel. Indeed, it is not to be borne, the humane sense of the community will not suffer it—revolts against it, and will certainly abolish it. Without doubt it is wrong to compel men, women and children, either by direct or indirect compulsion, to submit to inoculation with small-pox, cow-pox, typhoid fever, plague or any other disease. As Professor Francis Newman has remarked: "Against the body of a healthy man or a healthy infant, Parliament has no right of assault under pretence of the public health; the law is an unendurable usurpation, a tyrannical wickedness, and creates the right of resistance." Without doubt it is wrong to compel medical men to violate the oath which they take on inauguration and to betray the most sacred secrets of their patients to the executive. Without doubt it is wrong by force to aggregate and imprison rich and poor alike—those who have ample accommodation at home, and those who have none—in so-called isolation hospitals.

Without doubt it is wrong to subject men, women, and children who have merely been bitten or licked by dogs or other animals to the awful risks of the hypodermic injection of rabid matter; upwards of 2,200 have already perished after undergoing the process, and although there is no compulsion in this case, public money is spent upon it, and it ought to be banned both in the interests of society and humanity. Without doubt it is wrong to inoculate healthy horses with glanders on pretence of seeing whether they have got glanders or not, or healthy kine with tubercle on pretence of seeing whether they have got tubercle or not, or with anthrax or tetanus on pretence of preventing anthrax or tetanus. Without doubt it is wrong to inoculate healthy horses (who are very prone to lock-jaw) with glanders, with tubercle, and repeatedly with the most malignant diphtheria merely to utilise the product so obtained in the treatment of sore throat. It is a mistake to suppose that the introduction of so-called antitoxin has resulted in a diminution in the mortality from diphtheria, and it is a mistake to suppose that Germany has secured

immunity from small-pox by repeated vaccinations, It was by the substitution of intubation for tracheotomy, and the use of the biniodide of mercury, as recommended by Dr. Luff, and the similar employment of the salicylate of iron as suggested by Dr Gray that diphtheria has been robbed of its terrors' and it was by the expenditure of hundreds of millions (the French indemnity) in hygiene and public works that Germany has secured comparative immunity from small-pox. "To insist on doing in one way that which can only be accomplished in another" was Pascal's definition of tyranny, and after all, when so-called science has said its last word, it is to hygiene and the strengthening of the vital resistance of the individual that we must look for such advance as is possible in the prophylaxis and treatment of disease.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

By T. P. Legg, M.S., F.R.C.S.

Tumour in the Thigh of Uncertain Nature.—A man, æt. about 47, was sent up to the hospital suffering from a swelling in the lower and outer part of the right thigh. The history was that twelve months ago he was struck in this part of the thigh by a motor car. Immediately after the injury, except for the bruising, he noticed nothing abnormal. Five months later the swelling was discovered, and had gone on steadily increasing to its present size, which was about that of a large orange. There had been no pain and no interference with the functions of the limb. On examination a firm elastic lobulated tumour was found situated in the muscles on the outer and anterior aspect of the right thigh in its lower third. The upper part of the growth had a well-defined edge, the lower edge was not very distinct. The skin was quite normal over the whole tumour and was quite free of the growth which, last could also be easily moved in a lateral direction over the shaft of the femur. On making the patient put the muscles into action the tumour became more prominent and harder. There was no sign of fluctuation, and the whole of the thigh was larger than the opposite one. On the upper and inner side of the same leg, about three inches below the knee-joint, there were two horse-shoe shaped ulcers separated at each extremity by a narrow bridge of skin; their edges were steep, sharp cut, and their bases smooth. There were no other lesions in other parts of the body, and the man looked healthy. What was the nature of the swelling? Mr. Legg said in diagnosing any tumour or swelling the first thing to make up one's mind upon was—where is the tumour? and not, what is it? This tumour was in the muscles. Now the only common tumour in a muscle was an inflammatory one, and in this particular case there was good evidence in the ulcers below the knee that the patient was suffering from syphilis, and the first impression would be that the mass was a gumma. Against this view was the fact that the tumour had been present so many months and had not yet involved the skin nor broken down into an ulcer; the alternative diagnosis to make was one of new growth, either a sarcoma or an innocent tumour such as an intramuscular lipoma. These latter were quite uncommon, and except for the lobulation there was really nothing to suggest a lipoma; besides, if the history was to be relied upon, it was unlikely that a tumour of this kind would have reached such a size in seven months. As regards the tumour being a sarcoma, the surgeon, Mr. Legg, pointed out, could only make such a diagnosis by a process of exclusion. Other possibilities, however, occurred, namely, that the swelling was a hæmatoma or ruptured muscle following the injury; but both the local signs and the history that nothing was noticed for five months after the accident were against such a diagnosis, and there was nothing to suggest a tuberculous nature of the swelling. Mr. Legg thought that inasmuch as the patient had not had mercury but only iodide of potassium, it would be advisable to put him on full doses of the iodide and also gr. ij. of hydrarg. c Creta twice a day for a fortnight to see if any effect were produced on the tumour. If there was no perceptible diminution in size, he considered that the best thing would be to cut the swelling out and ascertain by microscopical examination, if necessary, the nature of the growth. In reference to what he had previously said regarding the differential diagnosis of inflammatory swellings from new growth, attention, he said, should be carefully directed to two points—first, the edges of the swelling, which in the former are generally not well defined, and shelve off gradually into the surrounding tissues; in the latter the edges are often defined, sometimes even steep, although these characters may not be equally marked in all parts of the swelling. The other point to which attention should be carefully directed was the lumpiness or lobulation of the swelling; for example, a lipoma was frequently definitely lobulated, a sarcoma was very often lumpy or nodular, and at an early period becomes fixed to adjacent parts. In the present cases, these points were well illustrated; lobulation was evident, there was a well-defined edge in one part, and not so well defined in the lower part, thus making the diagnosis obscure, and in such cases all the factors have to be considered. As he had already pointed out, the man was suffering from gummata, and it was always a rather risky thing to diagnose two diseases in thesame patient at the same time, unless the evidence of each disease were indisputable, so that the first thing in this patient was to exclude by a therapeutical test if possible that the swelling was a gumma. Sometimes gummata do not yield readily to anti-syphilitic treatment, and therefore as there was a doubt in the diagnosis, further means to determine the nature of the swelling must not be unduly delayed.

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

Removal of the Whole Upper Extremity.—Mr. McAdam Eccles operated on a man, æt. 40, who nine months before had noticed a small hard swelling at the back of the upper part of the right arm immediately below the axilla. When seen there was a large fluctuating swelling simulating a synovial cyst. On exploration a growth was discovered, but the patient would not submit to its removal at the time. Shortly afterwards, however, he consented to the removal of the upper extremity which was considered the best means of eradicating the disease. The skin incisions had to be so planned that the longer flap was obtained from the front and outer side of the shoulder; a semilunar incision was therefore made from a point just internal to the middle of the clavicle outwards over the shoulder and down the arm to the insertion of the Deltoid. The clavicle was then sawn through at the junction of the inner with its outer two-thirds and the third part of the subclavian artery exposed, ligatured in two places and divided between; the subclavian vein was treated in a similar way. The brachial plexus was next severed, the connective tissue in the axilla torn through and both Pectoral muscles divided close to their insertions. A second incision was now made from the middle of the clavicle downwards and backwards over the scapula to meet the lower end of the anterior incision. The transversalis colli artery having been ligatured, the Trapezius, the Levator Anguli Scapulæ and the Rhomboids were cut across, the Omo-hyoid being the last muscle to be severed. The whole upper extremity was now detached and quickly removed. The patient did not show any signs of shock. All small vessels that exhibited any tendency to bleeding were secured and the skin flaps brought together and retained in position

by silkworm gut, interrupted sutures, and a drainage tube was inserted at the lower and posterior angle of the wound, the rest being sealed by gauze and collodion dressing. Mr. Eccles said that removal of the whole of the upper extremity was fortunately a somewhat rare operation, seeing that the mutilation was very great. Sarcoma was the chief indication for the proceeding. The new growth in this case had commenced at the origin of the long head of the Triceps and had been associated with a large blood cyst, which obscured the growth itself and gave rise to an erroneous impression that the case was one of a simple synovial cyst. Having decided upon the necessity of the removal of the whole of the upper extremity Mr. Eccles said he was confronted with the difficulty of planning his incisions in such a way as to secure enough skin and yet to keep very wide of the region of the growth. Division of the clavicle early in the operation and prompt ligature of the subclavian vessels were, he considered, important steps, as they enabled the operation to be carried out with a minimum loss of blood and consequently with the slightest amount of shock. The cords of the brachial plexus, he said, should be divided close to their exit, from between the Scaleni muscles so that the future bulbous ends might not be pressed upon by any artificial apparatus that might be applied. Drainage for the first twenty-four hours was, he thought, generally advisable and, if asepsis had been obtained and maintained, healing would be rapid and convalescence short.

The tube was removed on the following day, only a small quantity of blood-stained fluid being drained away. The patient made an uninterrupted recovery, the temperature never rising above normal and the wound being healed throughout in ten days; the man left the hospital twelve days after operation.

AMPUTATION AT THE HIP JOINT.—On the same afternoon the same surgeon amputated at the hip joint the right lower extremity of a young man, æt. 19, for Infantile Paralysis. The limb had been useless since the patient was two years of age and had been constantly the site of trophic ulceration and of inconvenience when walking. Mr. Eccles made a circular incision at the junction of the upper and the lower two-thirds of the thigh cutting through all structures down to the femur, pressure meanwhile being exercised by an assistant's finger on the femoral artery at the level of Poupart's ligament. The main vessels of the limb were then secured. In doing this Mr. Eccles said it was interesting to note that owing to the trophic changes brought about by the paralysis, these vessels were very small (the artery being not more than the size of the upper part of the radial). An incision was then made down the outer side of the limb from half way between the crest of the ilium and the top of the great trochanter to meet the circular incision. The muscles (atrophied) were rapidly raised from the bone in front and behind, and the head of the femur disarticulated. All further bleeding vessels were tied and the flaps united both along their vertical and their transverse edges with silkworm gut interrupted sutures; the wound was dressed without drainage with a collodion and gauze covering. Mr. Eccles said it was interesting to have an amputation at the hip joint on the same afternoon on which he had performed removal of the whole of the upper extremity, these two operations being the most severe amputations in surgery. This second case, however, was one of an atrophied limb and consequently the shock was far less than it would have been in the case of a patient with a normal lower extremity. The first essential, he considered, in an amputation at the hip joint was to secure asepsis, which was not altogether easy because of the nearness of the wound made by the surgeon to the genitals and anus. He thought that the method he had employed—namely a circular division at the junction of the upper with the lower two-thirds of the thigh together with a vertical incision on the outside was the best plan. He pointed out that the circular incision was made very much higher up than in the usual description of Furneaux Jordan's operation, and he stated that he considered that most text books on operative surgery placed the incision much too far down the limb—namely, in the lower third of the thigh. In amputating at the hip joint when the limb was not atrophied. Mr. Eccles said he would use drainage for the first twenty-four hours. Disarticulation at the hip joint for injury, he pointed out, had a very heavy mortality, but removal of the limb at this joint for disease was not nearly so dangerous to life as was usually thought.

The stitches were removed a week later, the wound was soundly healed in a fortnight, and the patient, being taught to walk with crutches, left the hospital eighteen days after the operation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 2nd, 1906.

DIAGNOSIS OF MENINGITIS.

DR. MONTAGNON, physician of the hospital at St. Etienne, read a paper before the Congress for the Advancement of Science, held last month at Lyons, on "The Research and Signification of Albuminous Reaction in the Cephalo-Rachidian Liquid Observed in Meningitis in Children."

Since Quinck advocated puncture of the rachis in the lumbar region in 1893, an excellent means of diagnosing meningitis has been added to those already at our disposition.

However, the study of the modifications of the cephalo-rachidian liquid in the different meningeal reactions had not yet attained sufficient regularity to be regarded as a sure means of diagnosing the nature of the reaction.

Yet in the majority of cases, the modifications observed (lymphocytosis, change in colour density, chemical composition) constituted very important signs of inflammation of the membranes when the clinical symptoms were, as it frequently happens, somewhat obscure and excusing a certain hesitation on the part of the treating physician both as to the nature of the affection and the gravity of the prognosis.

That research was particularly useful in children so subject to inflammations of the coverings of the brain, and for which the attendant was always anxious to pronounce with probability as to the mildness or gravity of the affection.

Although it cannot be said that a sure and infallible sign has yet been discovered, yet the lumbar puncture, in the majority of cases, persisted in uniting the signs furnished by the examination of the different modifications of the cephalo-rachidian liquid, to arrive at a very precise diagnosis.

Many an attendant, says Dr. Montagnon, has been embarrassed at the bedside of the patient to know if he had before him a case of true meningitis or one of those cases of pseudo-meningitis giving clinically all the symptoms of tuberculous meningitis, yet how different in their termination.

Heretofore, before the lumbar puncture was practised, many cases of tuberculous meningitis were cited as cured which were in reality but the pseudo cases already mentioned (reflex, vermicular, or of hysterical origin).

Up to the present, the presence in excess of lymphocytes in the cephalo-rachidian liquid had been regarded as characteristic of the gravity of the disease.

Still more recent researches tended to prove that the presence of numerous polynucleares in the liquid coincided with the aggravation of the malady.

Finally, an excess of albumin in the same liquid, as observed by Dr. Montagnon, would seem to constitute the best sign in making a correct diagnosis and prognosis of meningitis.

In the normal condition, a small quantity of albumin is found in the cephalo-rachidian liquid (0·20 per cent.) corresponding, when treated with a few drops of nitric acid, to a very slight cloud. But when the membranes are inflamed, the quantity of the albumin increases notably.

Of four cases treated recently by Dr. Montagnon, three terminated fatally and the fourth made a good recovery. In the former, the increase of albumin in the cephalo-rachidian liquid was intense and progressive, while in the latter, which clinically presented the same symptoms, the cytologic and albuminous reaction were normal.

It is evident that the only certain proof of tuberculous meningitis is the presence of the bacilli of Koch, but with the signs already referred to and particularly that of albumin in excess, presumption may yield to certainty.

An excess of albumin may consequently be considered as the synonym of intense inflammation of the membranes of the brain and as meningitis in children is almost always (98 per cent.) tuberculous, the increase of albumin in the liquid is the equivalent of tuberculous meningitis.

Thus each time, concluded Dr. Montagnon, that children present some signs of inflammation of the brain, the lumbar puncture should be made and the liquid examined for albumin; if it is found in excess the prognosis must be grave, if on the contrary and in spite of alarming clinical symptoms no more than the normal quantity of albumin is found to be present, a favourable opinion as to the issue of the malady may be entertained.

Treatment of Scabies.

Carbonate of soda, 1 oz.
Sulphur flowers, 3 ozs.
Glycerine, 6 ozs.
Gum adragante, 15 grs.

The patient rubs himself with ordinary soap for half an hour, then takes a bath, followed by smart friction with the above mixture. The following day and for two or three days afterwards, the patient will take a starch bath (one pound of starch for each bath), and powder himself with the same substance.

GERMANY.

[from our own correspondent.]

Berlin, Sept. 2nd, 1906.

A New Method of Gastrostomy.

Prof. Favel, of Berne, has recently published notes of a new method of performing the operation of gastrostomy to which a reference is made in the *D. Med. Zeitung*, No. 66, 1906, as follows: All the older methods of performing the operation have the disadvantage that the opening made closes easily or becomes small, and that the wall of the stomach is fixed to the abdominal wall. This can be avoided when the stomach is attached to the skin by the intermediary of a loop of intestine, that is, allowed to retain its mesenteric attachment. This is formed like a new œsophagus, with its peristaltic action functionising towards the stomach. The only disadvantage of the operation is that it takes up a longer time than the other method.

Meat Poisoning and Gastric Crises.

From the same journal we note a serious and suggestive case taken from the *Charitee Annalen*, 30 Bd., S. 98. A man, æt. 31, after partaking of meat that was suspected of not being good, was attacked by severe abdominal symptoms, which were held to be the result of his partaking of unsound food. Later on, however, it was discovered that the attacks were really due to commencing locomotor ataxy, and were the usual gastric crises of that disorder. The patient died, and the autopsy confirmed the later diagnosis. On the ground of a medical opinion that favoured the poisoning theory the patient had entered an action against the butcher who sold the meat, claiming for bodily injury resulting from the use of it. The butcher gained the verdict as regarded poisoning by unwholesome meat, but he was convicted of unlawful proceedings otherwise as regarded the meat (the addition of boric acid).

Bier's Stasis in Diabetes.

Dr. Karl Grube has a paper on this subject in the *Munch. Med. Woch.*, 29, '06. Bier's hyperæmia is such an important matter that it has been declared to be the greatest advance made in clinical surgery since Lister's introduction of asepsis. The author has employed the process in diabetics both in milder and severer cases, as well as in furuncles and carbuncles and has found that as compared with other lines of treatment it has many advantages, that it is less severe, that it leads more rapidly to healing, and that in severe cases it seems to protect against the onset of coma.

Latterly the writer has treated diabetic gangrene by hot air, and very successfully. The foot or extremity affected is exposed to hot air for an hour each day. The temperature of the air is from 60 to 65 C.; higher temperatures are not necessary, and they may even be injurious. The action is this: The pain that is often very severe disappears usually after even a few sittings; the feet, previously livid and cold, take on a normal appearance, and any ulcers present usually show a tendency to rapid healing. It is an especially good sign, too, when the feet which had hitherto remained dry, showed a tendency to sweat. When carried out properly, the writer has never seen any bad results following it, but, on the contrary, frequent improvements. He has carried out the treatment in about twenty cases. It is necessary to watch the cases carefully, whilst the treatment is being carried out.

The *Charitee Annalen* contains also the following cases of interest on account of their being unusual terminations to perityphlitis: A man, æt. 39, had first symptoms of perityphlitis a year after he had been relieved of his appendix vermiformis. An operation showed the presence of adhesions, after the separation of which recovery took place. In another case the valvula Bartini closed up from chronic perityphlitis. The patient died from collapse after the operation that was performed for the relief of the condition. The third case was remarkable in that the perityphlitis was complicated by the hæmorrhagic diathesis. Hæmorrhages took place from the stomach, intestines, nose, kidneys, and skin, and to this the patient finally succumbed. In the fourth, pyopneumothorax resulted from a perityphlitis without any perforation of the diaphragm. It probably arose in connection with a development of gas from colon bacilli. A large quantity of pus was set free at the operation. In a fifth case, the interest lay in the onset of a perityphlitis in a pregnant woman (premature labour), and in the peculiar route taken in the evacuation of the pus—through the labium majus. In the fourth case recovery took place after bursting of the collection into the bladder. In the last case after a 10 pfennig piece had been passed *per via naturales*.

An interesting point is that not infrequently groups of cases appear as during an influenza period, for instance. As regarded diagnosis the writer had only made use of the counting of the leucocytes along with the other clinical symptoms. The comparison of the temperatures in the axilla and that in the rectum was scarcely likely to aid diagnosis. Therapeutically, morphia was advisable, as it relieved pain without

materially influencing peristalsis. Operations were undertaken when the exudation was extensive, when the general symptoms were grave, and when symptoms of threatening perforation were present.

AUSTRIA.

Vienna, Sept. 2nd 1906.

RÖNTGEN DIAGNOSIS.

JAKSCH, at the Prigue "Verein," related his experience in the diagnosis of disease by means of the Röntgen rays. Three hundred cases had come under the radioscope and every one of them had distinctive feature for diagnosis. Pyopneumothoras and tubercle can be diagnosed by the peculiar shadow of the latter, scars of old tubercle that have healed are clearly distinguishable in the pulmonary tissue. In cases of pneumonia the daily progress of the infiltration of the lung can be accurately followed and confirmed by percussion. The solution of the solidification commences in the centre, as a clear space in the shadow which coincides with the fall of the temperature. Atelectasis has the same general outline as infiltration, but the former is slightly clearer. Pleuritis and tumours are easily diagnosed, but anything in the mediastinal space is hard to differentiate. Mammary carcinoma may be mistaken for a tumour in the lung. In the case of pneumonia from the presence of a foreign body the latter could not be observed, while the pneumonia could be easily diagnosed. He admitted that infiltration, atelectasis, and fibrinous pneumonia were difficult to differentiate and required further physical examination. In cardiac disease the size of the heart is the only information obtainable. Hypertrophy, aneurysms, and atheroma in the peripheral vessels were shown in photos produced. A special case of atheroma tibial postica or what Charcot gave as the cause of Claudication intermitt nt was well illustrated. Basedowii, hepatitis, acromegalia, etc., with syphilitic cicatrices in the interstitial tissue of the liver.

Eckstein drew attention to the case of the foreign body in the lung that could not be discovered. It turned out to be part of a nutshell that had passed down the bronchi. He thought this difficulty was due to the equality of specific gravity as the nutshell was about the same as the lung. With a foreign body of a different specific gravity, the difficulty would have been less.

The same hypothesis prevailed in all diseases of the liver. He would assure the meeting that fine tuberculous centres were not so easy of diagnosis as Jaksch would have us believe. His method of ventrodorsal examination is sometimes unavoidable, but for accurate diagnosis of the apex of the lung the dorso-ventral is the more exact, as it obviates the error or confusion caused by the osseous structure and thick muscles of the neck. Again, the lung should be taken in a state of repose, and not with one or two minutes of exposure. This obviously leads to an error where fluids are present as he pointed out in his demonstration.

VIRULENCE AND AGGRESSION IN TUBERCLE.

Oscar next related his experiments with tubercle in guinea-pigs. After the disease has been imparted to an animal there is a period of hyper-sensitiveness when a new quantity of the bacilli injection suddenly reacts on the animal and speedily kills it. The post-mortem reveals an exudation in the peritoneal cavity which contains lymphocytes but no phagocytes. If another animal not in this hypersensitive condition be injected with a larger amount of the bacilli it may not or it may slightly affect the animal which will live through a protracted illness and finally die. When examined in the same way a very large number of phagocytes will be found in the exudation.

Again, if a small quantitv of the infecting bacillary fluid be injected along with the serum of a hypersensitive animal, into another guinea-pig acute tuberculosis will be induced. In this case no phagocytes will be found, or, if found, will be in small numbers at the very end, while large quantities of leucocytes will be found at the centre of infection.

Virulence and aggression are, therefore, different quantities. "Aggressivität" inhibits the concentration of the leucocytes around the infected centre and prevents the phagocyte from protecting the hypersensitive host.

The hypersensitive animal is one without that power of resistance against any new invasion of the bacillary poison, or where no phagocytes are present to take up the defensive immediately and destroy the new force brought suddenly into the field. The action of this poison is to increase the circulation at the centre which admits of rapid action when tuberculin is injected to counteract.

At the beginning of a tubercular attack this power of "Aggressin," is small and allows the body time to prepare for resistance, but as time goes on this aggressive power becomes stronger and finally triumphs.

LETTERS TO THE EDITOR.

THE SUPPRESSION OF QUACKERY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—My statement that no editor of a lay paper dares nowadays to attack quackery evidently needs qualification. A very important exception must be made. *Truth* is with us; the Editor knows the extent and magnitude of the evils we seek to combat and if he will take up the question with the vigour he has displayed in other similar enterprises the hope of ultimate success must be, to say the least, very largely increased. As there seems a danger of some little misunderstanding of my suggestions, I should like to repeat that I propose that our energies be first of all directed entirely to the demand for a Royal Commission. Unless this is kept in view all other efforts will be thrown away. There will be no difficulty in producing overwhelming evidence as to the urgent necessity for medical law reform, and for legislation to control the quack's medicine trade. The movement cannot be successfully carried on without the sympathy of the profession as a whole, and perhaps the co-operation of representative professional bodies. I should hope that it would in due course be taken up by the British Medical Association. The Association might help provide funds. A large sum will be needed. Five to ten thousand pounds would, I think, not be too much to ask for. Some of this, or a great part, might be drawn in the end from the public. If by the activity of *Truth* and other agencies, the facts regarding the cruelty of quackery and the misery it is inflicting upon simple sufferers were exposed there could be hardly a doubt that many wealthy philanthropists would be induced to help. But I repeat, the profession, if help from outside be refused, is quite able to do the work itself. The great bulk of medical men are poor, but there are enough who can afford to contribute to a fund, and a minority whose large incomes should enable them to find all that is needful themselves. If the movement progress an executive body must be constituted to direct the movement, and, on the granting of a Commission by Parliament, to gather and arrange evidence and present it properly before the Commission. It is here that money would be needed. Counsel would probably have to be engaged, witnesses skilled and unskilled, of certain classes, would have to be paid, whilst a large expenditure would be involved in the analysis of the various classes of medicines the authoritative exposure of the composition of which would suffice to demonstrate their harmful and fraudulent character.

I am, Sir, yours truly,

HENRY SEWILL.

August 30th, 1906.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A medical leader writer on the staff of the *Times* contributes an article on August 21st on the subject of sanitary administration by local authorities. The article is really an indictment of the authorities,

all of whom neglect, more or less, and some neglect entirely, the duties they are morally bound to carry out. The people, too, are in many instances to blame. "They will take quack medicines by the gallon," but will not compel their local rulers to carry out the elementary necessities of sanitation prescribed in Public Health Acts. The writer emphasises the recent utterances of Dr. Ray Lankester at the British Association anent the urgent need to teach our people "to make use in public affairs of the kind of knowledge called science." What must be the feelings of this able writer when he turns to the advertising columns of the great paper on which he is employed and finds there the puffs of the quack medicines which "the people take by the gallon," showing thus their scorn of the science he is engaged in upholding. I do not speak of the issue of the *Times* of August 21st, but of those within the past few years. During all this time advertisements of quack medicines have constantly appeared the character of which must have shocked the writer of the leader in question as well as every man of the world engaged upon the great journal. Is it possible the managers had not learnt from these gentlemen the nature of the quack medicine trade, that they have not had their attention called to the articles (quoted lately in the Medical Press) in which the traffic was denounced by their own editors in the strongest terms. If people "swallow quack medicines by the gallon," it is very largely due to the fact that they are advertised in the *Times*.

I am, Sir, yours truly,

An Obscure Practitioner.

August 24th, 1906.

THE DECLINING BIRTH-RATE.

To the Editor of the Medical Press and Circular.

Sir,—It is probably due to my density rather than to Mr. Clement H. Ser's lack of lucidity, but I must confess I do not understand his statement and argument. We have at any rate in France a complete object lesson in the effects of artificial restriction of population both upon individuals and upon the State. We are following the example of the French, and there can be no doubt that if we, like them, push it to its logical conclusion similar efforts will be produced. The French are a dying race. Their wealth accumulates whilst their men decay. Fifty big signs and symptoms and five hundred smaller ones can be adduced to prove their moral decadence. They have through lack of numbers alone forfeited their place as the leading European power, and have rendered impossible the establishment of a French Empire. Owing to this same cause their stationary 38,000,000 against Germany's 61,000,000 and 800,000 annual increase, they would if without allies lie at the mercy of their enemy. If Europe did not stand between her and her hereditary foe there can be no doubt France would be soon compelled to yield up her vast oversea possessions to which she has no men to send, and in which there is room for vast millions. Madagascar alone could take all Germany's increase. The climate in great part is suitable to Europeans. It is certain that England or Europe will not be able for ever to prevent the deserved spoliation of France by a more virile race; and it is certain that no power will prevent the British Empire from undergoing a similar fate if we do not become prepared to people our vast colonies, where there is room for our overflow for the next five hundred or thousand years. A correspondence now going in the *Times*, and contributed to by Australians of statesmanlike rank, makes clear that the facts are recognised. If we do not people these lands we shall in time lose them. The efforts of statesmen and the nation ought to be directed not to the restriction of population but to the solution of the social problem. A residium there may always be, but the numbers of the unemployable classes can be reduced by known methods; the physical, mental, and moral qualities of the people can be improved, and for every one of the unemployed a place can be found among kith and kin beyond the seas. A truly mighty British Empire can be built up only in this way; without an exuberant population, nothing can save it from destruction.

I am, Sir, yours truly,

Imperialist.

August 29th, 1906.

BELFAST.

[from our own correspondent.]

Belfast District Lunatic Asylum Annual Report.—Dr. William Graham's annual report is always an interesting document, as it deals not only with the questions of management and finance, but also with the increase of insanity and its probable causes in Ulster. The asylum population under his care has increased 37 last year, from a total of 1,071 to 1,108. The first cause of the increase is attributed to the greater comfort of the modern asylum, the recognition of this bringing a larger number of cases of senile insanity, no less than 25 admissions having been over 65 years of age. The cases of congenital mental deficiency also increased, and Dr. Graham looks forward to a still greater increase when the Royal Commission on the Care and Control of the Feeble-minded reports. As regards the supposed general increase of insanity, he does not seem to think that it has much to do with the "increased pressure of modern life," and such causes as are often connected with it. He points out that the intellectual classes furnish the smallest proportion of cases, and that his patients come mainly from the very poor, among whom bad food, alcoholic indulgence, and vicious moral environment play a sinister role. The question of the part played by alcohol is touched upon, and Dr. Graham is evidently inclined to look on alcoholic indulgence more as an early symptom of unstable mental equilibrium than as a great cause of insanity. The part of the report dealing with the prevention of insanity is most interesting, and the suggestion is made that it would be a good thing to get rid of the word "asylum" with its old associations of some transcendental causation for insanity, and use some such term as "hospital for brain diseases." In one thing, and one only, Dr. Graham sees hope, and that is the spread of education, and specially the spread of the knowledge of elementary physiology, which will prevent the marriages from which the mentally unsound are derived. He may be right, but we fear that while "Love laughs at locksmiths" he will also laugh at professors of physiology.

OBITUARY.

DR. E. T. WHITAKER OF SHREWSBURY.

The death occurred last week at White Lodge Shrewsbury of Dr. Edmund Thomas Whitaker, medical officer to public bodies at Shifnal, Oakengates, Wellington, Ellesmere, Cleobury Mortimer and Burford, Salop. He held similar appointments at Tenbury and Rock, Worcestershire and also advised the Denbighshire and Montgomery County Councils. He was keenly interested in all public health matters. Dr. Whitaker was an ardent student of Esperanto and did much towards forming a branch of the Esperanto Society amongst British medical men. He was a son of Dr. Edmund Whitaker, of Bacup, and obtained his M.B. and C.M. degree at Edinburgh University in 1894 and the D.P.H. Cantab. in 1896.

EDWARD JAMES ADKINS, M.R.C.S., Eng.

We regret to note the death of Mr. Edward James Adkins, son of the late Mr. J. E. Adkins, surgeon, of Yealmpton, who died on the 19th ult., æt. 53. The deceased was a popular and esteemed member of the Hastings medical profession. He had been in failing health for about two years, but his last illness only extended just a month. For some time he had been in partnership with Dr. W. E. Peck, and went to

Hastings from Yealmpton about twenty-four years ago. Deceased leaves a widow and family, the eldest son, Mr. Stanley Adkins, being at present in Canada. Deceased was educated at Guy's Hospital, whence he took the membership of the English College of Surgeons in 1875.

THOMAS PONSFORD CANN, M.D.DURH.

WE regret to note the death of Dr. Ponsford Cann, at the early age of 31. He was a native of Newhaven, and by his death the town has lost a prominent and highly respected inhabitant. As recently as 5th June last, the deceased's father died. Born in 1874, Dr. Ponsford Cann was educated at Durham University, where he graduated M.B in 1899, and subsequently acted as assistant to his father, who was also a medical practitioner. Since the latter's death he had carried on the practice at Newhaven, until about three weeks ago when he received a prick from an instrument while operating upon a patient—removing a tonsil. Pain in the finger was followed by unmistakable evidence of blood-poisoning, and despite everything that Dr. C. L. Brown and other medical gentlemen could do for him he died late on August 27th. He held many appointments in the district, including those of Medical Officer of Health to the Newhaven Urban District Council, to the Board of Alien Immigration, the Port of Newhaven and the Town, &c.

REVIEWS OF BOOKS.

DIAGNOSTIC METHODS (*a*).

THE University at Berne has in recent years established for itself in this country a well-earned reputation as a medical teaching centre. Until quite recently it was far more celebrated as a centre of surgical than of medical teaching, but since the work of Prof. Sahli has become known the honours have been more equally divided. Prof. Sahli is now justly recognised as one of the foremost teachers of clinical medicine on the Continent. It is now just twelve years since the first German edition of Prof. Sahli's book appeared, and during that time three subsequent German editions have been published. We must heartily congratulate Saunders and Co. for their enterprise in undertaking an English translation of the work, and thus making it more readily accessible to the practitioners of this country.

Though described as a text-book of diagnostic methods it is not, as Prof. Sahli points out, a mere compilation, and indeed a study of the work readily convinces one that the warning is unnecessary. There is much in the book that is quite new, and everything is treated with a directness that emphasises the personality and experience of the writer. It is not possible for us in the space at our disposal to pass in review the many excellent points in this work, and it will be sufficient if by the mention of one or two we induce our readers to study the work for themselves. We should like first to point out that almost every diagnostic method at the disposal of the clinician is here treated of, and its value appraised. Cystoscopy and the X-ray examination the author has omitted, not because he undervalues these methods, but because he has not had "sufficient practice and experience to justify the effort to teach them to others."

In judging of the value of a text-book of diagnostic methods we habitually first turn to the subject of auscultation for the way in which an author treats of this subject usually gives a very good indication of the value of his teaching. There is, perhaps, no subject in medicine which is so important for the beginner, and yet none which is suually so inefficiently explained. The student is bewildered with a number of long names, to none of which do two authors appear to attach exactly the same meaning. In the work before us the normal and abnormal sounds are clearly described, and the significance of the latter explained, but we cannot acquit the author of the charge of adopting an extensive and somewhat puzzling nomenclature, nor can we always agree with him in his explanation of the causation of the sounds. Though this is so, yet the descriptions are always admirable, and the reader is never for a moment left in doubt as to the author's meaning—which is much more than can be said in the case of most text-book writers. It must not for a moment be thought that we look on Professor Sahli's book as a mere text-book of diagnostic methods, or that its value is to be judged merely by its description of such methods; it is in reality much more, and its value largely depends on the admirable physiological and medical teaching which it contains.

A word of praise must be given to the translator, Dr. C. P. Flint, who appears to have done his work admirably, sacrificing neither the meaning of his author nor the decencies of the English language. We could wish the publishers had seen their way to make the book as easy to hold as it is to read, for while the matter would tempt us to study it in the arm-chair, the form compels us to sit at the table.

(*a*) "A Treatise on Diagnostic Methods of Examination." By Prof. Dr. Hermann Sahli, Director of the Medical Clinic, University of Berne. Edited with additions by Francis P. Kinnicutt, M.D., and N. Bowditch Potter, M.D. Authorised translation from the fourth revised and enlarged German edition. Philadelphia and London: W. B. Saunders and Co., 1906. Pp. 1008.

SHIPMASTER'S MEDICAL HELP. (*a*)

THE third edition of Mr. Johnson Smith's well-known manual of medical advice for shipmasters is before us, a proof in itself that the work is appreciated by the class for which it caters. Indeed except for the official *Ship-Captain's Medical Guide*, which constitutes part of the outfit of every ocean-going ship, we believe that Mr. Johnson Smith's book is the only one that seeks to guide the medically-minded skipper in his amateur ministrations to the crew. The lot of the seaman who falls dangerously ill on a ship which is not likely to see land for several weeks is one that is not pleasant to contemplate, and every ship's surgeon who has regaled himself on a long voyage with reading the official handbook will bear witness to there being many things medical not included in its philosophy. A book, then, that describes illness and injury with more care and detail should have a real field of usefulness, and such a book is this of Mr Johnson Smith's. It must have been a difficult one to write, for the average skipper's mental compass is not of the widest, and culture does not flourish a-shipboard. So that a great deal of writing down has to be done, if modern pathology is to be made acceptable to the mercantile marine brain. On the whole we think that Mr. Johnson Smith has "got there" more often than most medical writers would have done, and he has probably achieved his success through a sympathy with sailor men born of his large experience at Greenwich Hospital. His descriptions are generally simple, his explanations lucid, and his directions for treatment put no great strain on the intelligence. We remark with especial pleasure that he deals very gingerly with drugs, or rather advises his readers to do so, and that most of the advice as to the management of medical cases is confined to hygienic and nursing directions. His intention has evidently been to prevent the enterprising skipper from venturing too far into the perilous domain of therapeutics, and it is certainly a wise one. One is, therefore, surprised that it should be recommended (p. 233) that 10 drops of laudanum should be given every four hours in sloughing chancre in inflamed chronic ulcer (p. 213), and again (p. 89) in diarrhœa, without any indication as to how long such dosage should be continued, and surely it is hardly prudent to advise (p. 235) one grain of grey powder to be

(*a*) "A Medical and Surgical Help for Shipmasters and Officers in the Merchant Navy, including First Aid to the Injured." By William Johnson Smith, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. Third edition. Revised. 6s. London: Charles Griffin and Co., Ltd., 1905.

administered every four hours in primary syphilis, even though salivation be watched for. On page 115 we encounter a list of rather weird antiseptics, and whatever we may think of the rest it seems not without danger to include turpentine without mentioning its other properties. The directions for disinfecting (p. 21 and 22) are a little antiquated in view of modern practice, and we note (p. 25) that a drachm is said to contain forty drops. In the Board of Trade scale of medicines and medical stores reproduced, it is stated that all the drugs in the list marked with an asterisk should be supplied with a red poison label. We see that carbolic acid and Pil Sapornis Co. are not so marked; and we think that this omission should be rectified. That, however, is a matter for the Board of Trade, and not for the author who merely reproduces their scale. We are glad to learn that the St. John Ambulance Association are making special efforts to attract officers and sailors to their classes, and such as do so will be glad to find in this volume some amplification of their lessons. On the whole the book is so good that we should be glad to see it made official by the Board of Trade, and we believe that doing so would be a distinct gain to the health and comfort of those that go down to the sea in ships.

MEDICAL ANNUAL AND INDEX. (*a*)

So well known and trusted by the profession that commendation of each periodic issue is unnecessary. The present volume is as good as any of its predecessors, and the contributors have in the main managed to combine a comprehensive view with a selective judgment. With such a variety of authors it would, of course, be impossible to expect a uniform literary style, but more careful editing might have avoided such "howlers" as "to onset" (page 548). The plates are so scanty that they might as well have been omitted A series of 16 stereoscopic plates—excellent as they are—to illustrate the radical mastoid operation shows a lack of a proper sense of proportion. There is a considerable difficulty in finding one's way through the volume, a serious drawback to any book for ready reference, and it is unpleasantly weighted with advertisements. We make these suggestions not in any captious spirit, but in the hope of rendering more useful future issues of a book already invaluable.

The present volume is closely followed by the "Synoptical Index" (*b*) for 1899-1904. The book is extremely convenient as a guide to the annual volumes, while it gives in the briefest form an enormous amount of valuable information under each heading.

WATERSTON'S STEREOSCOPIC ATLAS. (*c*)

PARTS IV and V more than maintain the reputation of this most interesting and original work. Part IV includes 51 views, of which 25 have been devoted to the upper limb and 16 to perineum and pelvis. The remaining 10 have been prepared from special dissections to show the lumbar region and the position of the viscera of the thorax and upper part of the abdomen from behind. The latter series should be of interest to every physician, who will also find simply invaluable reference material in the localisation areas of the brain, as figured and mapped out in Part V. Much of the physiology and pathology of the nervous system is necessarily abstract, but the learner will find in Waterston's stereoscopic views a graphic map of the intricate field he is exploring. The demand for this series by teachers and students of medical matters, whether qualified or unqualified, is sure to be great. We congratulate both author and publishers upon the way in which this laborious and monumental work has been carried out to the standing credit of British medical literature.

THE COMBINED TREATMENT IN DISEASES OF THE EYE. (*a*)

IN this small book Dr. Burnham gives us the details of what he calls his combined treatment of disease. It consists of the administration of mercury and iodide of potassium internally with sub-cutaneous injections of pilocarpine. The author relates many cases in which he got good results from the treatment. They included rheumatic, syphilitic and gonorrhœal diseases of the iris and ciliary body, various forms of kirato-iritis and cyclitis, calcareous degeneration of the cornea, corneal opacities, conical cornea and sympathetic ophthalmia.

As there are many niceties in the administration of the treatment, which the author insists upon, those who think of trying the combined treatment are recommended to consult the original.

RUHRAH'S DISEASES OF CHILDREN. (*b*)

THIS is a remarkably concise little volume dealing with a wide subject. The method adopted by the author is to treat each subject with systematic notes, which are fuller in the more important maladies. In this way the reader is furnished with a compact guide which is at the same time trustworthy and well informed. There are a number of good illustrations. The publishers may be congratulated on having produced an excellent hand-book for students and practitioners.

INJURIES TO THE NOSE, AND ITS ACCESSORY CAVITIES. (*c*)

THE book under review contains in all some 130 pages, and the author has collected a good many cases to illustrate the various accidents. The book is divided up so as to be easy for purposes of reference, and has headings in the margins, a point which might well be copied in medical works. After fully describing the signs and symptoms of the various injuries he details several operations and methods of treatment in each of the different classes. The last chapter is devoted to the consideration of the insurance question, and what prognosis should be given as to ultimate deformity and what likelihood there might be of danger to life or total disablement. The book can be recommended as useful for reference in any case where difficulty may be experienced in deciding as to the best form of treatment.

AN outbreak of typhoid has occurred at Pontypool the cause of which is at present obscure. The various water supplies have been analysed, and notices issued urging the public to boil all milk and water, and to use the greatest care as to the cleanliness of the receptacles in which they are kept.

SAMUEL TANSLEY, a sorter at the Northern District Post Office, Upper Street, Islington, was fined £5, at Uckfield last week, for exposing his child without proper precautions when she was suffering from diphtheria. He was in the neighbourhood on a holiday.

DEDUCTING deaths of infants which were to a large extent not preventable, Dr. Reginald Dudfield, the borough medical officer of health, considers that 197 lives were locally last year "wasted." "Much of this wastage," he adds, "is due to carelessness and ignorance, and ought to be obviated."

MEDICAL NEWS IN BRIEF.

National Federation of Meat Traders' Associations.

THE biennial meeting of the National Federation of Meat Traders' Associations was held last week at Newcastle-on-Tyne, under the presidency of Mr. R. H. Brechin, Glasgow, who said that the question of direct Parliamentary representation had been considered, but it was thought that further consideration should be adjourned to the annual meeting. Mr. W. Coggan moved that, having regard to the fact that, pending the issue of the report of the Royal Commission on Tuberculosis, the Government emphatically declined to promote or facilitate legislation in relation to the seizure and confiscation of the carcases of animals alleged to be tuberculous, the federation would most respectfully urge upon the Government the necessity for issuing forthwith the report of the Royal Commission, in the interest of master butchers throughout the kingdom, who were suffering the most serious loss and inconvenience. He said that if there were no danger from boiled milk, surely there could be none from roasted meat. There was not a single case in which a medical man could say that consumption was brought on through eating tuberculous meat. They had thus a good deal to urge against the losses to which they were subjected. Mr. D. Rose, of Birmingham, seconded the motion, which was carried. It was resolved to oppose the Public Health (Regulations as to Food) Bill and Lord Donoughmore's Public Slaughterhouses Bill. In a discussion on Sunday trading, the feeling of the meeting was against opening butcher's shops on Sundays. Uniformity in swine removal orders was also urged.

An Overdose of Laudanum.

MR. BERNARD REECE, Cardiff deputy-coroner, held an inquest on Wednesday last on the body of Isaac Jones (30), who died as the result of poisoning on the previous Monday night. William Jones, deceased's brother, said he saw the deceased a fortnight ago and again just before his death. He was on the former occasion in "extra good spirits," and witness had never heard him threaten to do away with himself. He had heard that his brother was in the babit of taking drugs and that he had suffered of latc from influenza and pains in the head. Mrs. Orchard, an aunt of the deceased. and also his landlady, said deceased went to his work 8 about 7.15 a.m. on the Monday, and returned about a.m. He told her that he had had "the sack," and he seemed upset. Witness went up about 4.15 o'clock, and found him unconscious. She then sent for a doctor and the police, and he died about 8 p.m. the same night. The bottle and tumbler produced were found in a drawer in his room. She did not know that he had been in the habit of taking drugs. James Murray, manager of a chemist's shop in Bute Road, said he served deceased with half an ounce of laudanum for toothache. Dr. Buist: There is no restriction in law, but don't you think it an improper thing to supply a man with such a quantity?—Certainly not. Dr. Buist: Well, I do, and I think it a serious matter. Dr. Buist in his evidence said he found deceased in an advanced state of coma, and antidotes were administered. Half an ounce of landanum contained sixteen grains, and a full medicinal dose was two grains. Death was due to laudanum. The jury returned a verdict of "Death from misadventure, owing to taking an overdose of laudanum."

Fleetwood Camp—Another Death from Enteric Fever.

ANOTHER officer—Captain G. R. Fitzgerald, of the 5th Battalion Royal Munster Fusiliers—has died from enteric fever contracted in the camp of the 3rd (Militia) Battalion Loyal North Lancahsire Regiment at Fleetwood. A few days before the camp broke up three or four officers became ill. Lieutenant Rix died in the bospital at Fleetwood on Saturday night. The attacks of the fever were confined exclusively to the officers' quarters. Not one of the men of the battalion was affected—indeed the camp was a most healthy one. It is generally agreed by those who have been making inquiries into the matter that either the food or the water was contaminated. The food has been found to be quite wholesome, and it is now stated that a temporary water-pipe was run up from the town main to the officers' mess and that this pipe is defective. Several leakages were found, and as the pressure was intermittent, it is possible that the sub-soil penetrated into the pipe. The War Office are understood to be responsible for the laying of the pipe. Then, besides this defective pipe, another possible cause may have been the use of one of the old-fashioned army water-carts, which was issued from the depot for the purpose of storing water for culinary purposes. It is suggested in some quarters that it was possibly used in South Africa.

L.C.C. and Consumption.

"An interesting medical departure is to be made by the London County Council medical officers when the London elementary schools reassemble after the summer holidays. To test the accuracy of statements that have been made as to the prevalence of consumption among London school children all the children in certain selected schools are to have their chests examined and to be measured and weighed. In view of the possibility of parental objections, the parents of all the children in these schools are to be asked to give their consent to the examination."

Whooping Cough Microbe.

THE microbe of whooping cough has, it is said, been discovered and cultivated by Drs. Bordet and Genjou, of the Pasteur Institute at Brabant, and it is hoped that a cureative serum will be found within a very short time. Professor Metchnikoff, of the Pasteur Institute, is delighted at the success of these two disciples of the great Pasteur. "I am all the more pleased," he said, to an interviewer, "that Dr. Bordet has been successful for the reason that he worked under me from 1894 to 1901. As to the practical results of their discovery, I hear that these have already been most encouraging. Whooping cough can now be diagnosed in the most certain manner, a thing which was not possible formerly Only the method requires to be carried out by a skilful bacteriologist. However, a simplified method will certainly be discovered in time, and what is more important, we shall find the serum, which will enable practitioners all over the world to cure a disease from which almost every child suffers during its early years."

Consumption in Germany.

Two years ago, an inquiry and consultation office was established at Berlin, with the object of giving advice gratis to persons afflicted with consumption. The report of this office for the past year has just been issued. Six physicians and eleven sisters attended the office ten times weekly; 15,661 persons were examined medically; and in addition, 18,644 visits were made to dwellings, 365 beds were granted, 2,765 persons were helped with their rent and in other ways, for purposes of observation, 804 persons were placed in hospitals, 622 children were sent to children's hospitals, 1,000 more to homes in the woods or other suitable places, and 8,200 dwellings where consumption had set its roots were rendered sanitary. The Bureau, altogether, spent something like 500,000 marks in its remarkable work of charity.

Infantile Mortality.

The Annual Report of Dr. D. J. Thomas states that at Acton the public health generally has been good, and the death-rate lower; indeed, only two London boroughs have a lower death-rate. Infantile mortality has been substantially reduced, thanks to the good work done by the lady health visitor, Miss Williams, the improvement being in the decrease of deaths between the age of three and twelve months.

Suspected Cholera in Berlin.

Uneasiness has been caused at Berlin by the death of a girl, eight years old, who is suspected of having died of Asiatic cholera. The body has been taken for examination, and her relatives have been carefully isolated. The child lived in one of the most insanitary districts of Berlin.

The Roumanian Leper.

The Roumanian who is afflicted with leprosy, and who was sent back to Frankfurt, is being carefully treated in the Frankfurt Hospital, and kept strictly isolated. Negotiations are on foot to have him transported back to England. It is said he acquired the terrible disease in Abyssinia, where he was at work on the railway. He is a gifted man, and speaks eight languages.

Epidemic at Toulon.

An epidemic of cerebro-spinal meningitis is raging among the military at Toulon, necessitating the evacuation of the barracks. Ten artillerymen succumbed this month, and numerous cases are in the hospitals.

Diptheria in Leicestershire.

The epidemic of diphtheria which has been playing such havoc in the village of Fleckney, Leicestershire, for the last three months, has now spread to neighbouring towns and villages. Cases have broken out in Market Harborough, Kibworth, Harcourt, and Medbourne. An inspector of the Local Government Board has visited the district, and every precaution is being taken to stamp out the disease. A house to house visitation is being made at Fleckney by Dr. Robinson, county medical officer, and Dr. Phillips, medical officer of health for the district, and in all suspicious cases injections of antitoxin are being made.

Scarlet Fever at Hyde.

An outbreak of scarlet fever of a serious type has occurred at Hyde. There are over seventy patients in the hospital. It is said that cases have occurred in homes to which children have been sent back after treatment at the hospital, and, in reply to a question on the subject at a meeting of the Council, Mr. Alderman Kenny said it was impossible to tell definitely when a patient was absolutely free from scarlet fever or from danger of infecting others, but every possible precaution was taken to avoid sending a child home before danger of further infection had disappeared.

Typhoid at Pontypool and Panteg.

For twenty years there had been little zymotic disease in the area of the Pontypool and Panteg Councils, particularly typhoid fever. However, in May of this year several cases of typhoid were notified, and since then over thirty cases have been notified in Pontypool. Sixteen cases are also reported in the Griffithstown district, two of which have since proved fatal. Up till the present every effort to trace the origin of the outbreak has failed. Samples have been taken of milk and water, and these have proved satisfactory. In the Panteg Council's area Dr. Essex and Dr. Mulligan have visited a number of cases, and are of the opinion that the water was the only factor in common to all the cases, and of this samples are being taken. At a meeting of the Council the members were of opinion that the water from the Penyrheol reservoir should be shut off, stating that it was very thick.

Registrar-General's Returns.

The deaths registered last week in seventy-six great towns of England and Wales corresponded to an annual rate of 14·6 per 1,000 of their aggregate population, which is estimated at 15,818,360 persons in the middle of this year. In the preceding three weeks the rates had been 12·0, 12·6, and 13·8. Table 1 of the Return shows, for the several towns, the death-rates in each of the last four weeks: it also shows for the week ended last Saturday the births, the deaths from several causes, and the death-rates from certain epidemic diseases.

Measured by last week's mortality, the highest annual death-rates per 1,000 living, were:—From all causes, 20·3 in Middlesbrough, 20·4 in Birkenhead, 20·6 in St. Helens, 21·2 in Salford, 22·0 in Hanley, and 23·0 in West Ham; from measles, 1·3 in Norwich, 1·6 in Huddersfield, 1·9 in South Shields, 2·5 in Burnley, and 3·6 in Salford; from whooping-cough, 1·6 in in Middlesbrough and 1·8 in Birkenhead; and from diarrhœa, 5·1 in St. Helens, 6·0 in Wigan, 6·2 in Birkenhead, 6·6 in Nottingham, 7·6 in Aston Manor, and 10·2 in West Ham. One death from small-pox was registered in Liverpool, but none in any other of the seventy-six towns.

In London 2,155 births and 1,352 deaths were registered. Allowing for increase of population, the births were 250 and the deaths 151 below the average numbers in the corresponding weeks of the previous four years. The annual death-rate from all causes, which had been 11·6, 11·7, and 14·0 per 1,000 in the preceding three weeks, further rose last week to 14·9. The death-rate in the four weeks ended last Saturday averaged 13·1 per 1,000, being 2·0 per 1,000 below the mean rate in the corresponding periods of the four years 1902–5.

According to returns from the Metropolitan Asylums Board and from the London Fever Hospital there were 3,051 cases of scarlet fever, 851 of diphtheria, and 101 of enteric fever under treatment in these hospitals on Saturday last (Table 3). The admissions during the week, as compared with those in the preceding three weeks, were as follow:—Of scarlet fever, 308 cases, against 413, 408, and 415; of diphtheria, 100 cases, against 140, 135, and 133; and of enteric fever, 7 cases, against 18, 17, and 26. Table 10, compiled and furnished by the Medical Officer of Health of the Administrative County of London, shows the number of cases of Infectious Disease that were notified in the County during the week ended August 4th, 1906.

Notification of Births.

The St. Pancras Borough Council have just issued a notice in which they state that they have resolved to adopt tentatively during three months a system of voluntary notifications of birth, and to pay to the father doctor, midwife, student, or other person attending upon the mother the sum of 1s, for notifying to the medical officer at the Town Hall, Pancras Road, the birth within 48 hours of its occurrence in the borough.

Death from Lead Poisoning.—The Borough Coroner, held an inquest at Hanley, on August 14th, on the body of John Marlow æt. 49, gloss placer, Cannon Street. It was stated that deceased had not been able to work since March last, and had been attended by two doctors. It had been known that he suffered from lead poisoning for a year or two, and he had taken medicines to secure relief. Medical evidence after *post-mortem* examination showed that death was due to disease of the kidneys, caused by lead poisoning, and the jury returned a verdict to that effect.

A fish merchant, charged at Yarmouth with attempted suicide was on August 16th stated by Dr. John Rollings, house-surgeon at the hospital, to have taken a larger quantity of oxalic acid—one ounce—and survived than there was any mention of in medical records of poison cases. The doctor also said that Smith undoubtedly owed his life to the promptitude of his sister, who instantly gave him salt and water. For days Smith, in a collapsed condition, had hovered between life and death, being only kept alive by injections of stimulants, his throat being closed.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

Absorption in the Large Intestine.—Most of the text-books of physiology teach us that almost the entire absorption of foods takes place in the small intestine, the large intestine absorbing little beside water. Mingazzini in 1900 carefully described the microscopic appearances in the cells of the villus during functional activity of absorption, the most noticeable feature being a collection of globules at the base of the epithelial cells, these globules afterwards finding their way into the veins of the villus. Bremer (*Journal of Medical Research*, July, 1906) describes exactly similar changes as taking place in the epithelial cells of the large intestine. The only difference as to the function of absorption between the small and the great intestine, he believes, is one of degree. He has observed the same cycle of events in each case—both spherule formation and ingestion by leucocytes. The process goes on both in the epithelium of the surface and in that of the glands, but is inhibited if excessive activity of the mucous glands occur. Bremer supports his description by excellent plates. R.

The Mechanism of the Closure of the Bladder.—Leedham-Green (*British Medical Journal*, August 11, 1906) publishes some observations intended to combat the current or Finger's theory of the mechanism of the closure of the bladder. Finger held that when the bladder becomes much distended, the pressure of the fluid gradually causes the neck of the bladder and the internal sphincter to yield, allowing the fluid to enter the posterior urethra. When this takes place, the sharply defined border between the bladder and urethra disappears, and a bladder neck is formed. Leedham-Green, having criticised the reasons which led Finger to adopt this view, gives certain skiagraphs of bladders containing metallic fluids. In all of these the shape of the bladder is globular or oval, never pear-shaped, suggesting that no bladder-neck is formed. The skiagraphs cannot be said to be conclusive, since it is not quite clear that they were taken in such positions as would render the bladder-neck, if present, evident. According to Leedham-Green the muscular control of the bladder rests almost entirely in the internal sphincter, which, in opposition to the ordinary view, he regards as a voluntary muscle. R.

Cholera Toxin and Antitoxin.—Brau and Denier have devoted careful study to the subject of the toxin and antitoxin of cholera (*Annales de l'Institut Pasteur*, July 25, 1906). When Metchnikoff and Rux published their original memoir on the toxin of cholera, a debate at once sprang up as to whether the toxin was intracellular or freely soluble. The present paper throws light on this, as on some other obscure points. The main conclusions arrived at are:—(1) In liquid media the cholera vibrio rapidly produces a soluble toxin. (2) The production of the toxin is associated with destruction of the vibrios. (3) This toxin is very active on injection into the veins, giving rise to a marked production of antitoxic bodies. (4) Venous injection with live cultures gives rise to a more marked production of antitoxins. (5) No distinction can be drawn between the toxin contained in the bodies of the microbes and that obtained in the liquid of the culture tubes. R.

A Cytolysin for Nerve Fibres. — Following on Bordet's discovery of the phenomenon of hæmolysis, various other forms of cytolysis have been described by various observers. To the list of bodies subjected to this process, Schmidt has now added medullated nerve fibres (*Annales de l'Institut Pasteur*, July 25, 1906). He employed for his experiments the sciatic nerves of frogs, injected into guinea-pigs. The nerves were prepared for injection by chopping into small pieces and pounding in a mortar with physiological salt solution. Schmidt found (1) that the repeated introduction of the emulsion thus obtained into the peritoneal cavity of guinea-pigs produced in the serum of the latter certain bodies possessed of a destructive action on the nerves of the frog. (2) This action shows itself after subcutaneous injection in the frog of the serum of the guinea-pigs thus treated, by disorders of locomotion, and histologically by marked changes in the medullary sheath, by multiplication of the nuclei of Schwann's sheath, and by breaking up of the axis cylinder. (3) The serum produces agglutination when mixed with the emulsion of peripheral nerves. (4) Some time after the introduction of the emulsion to the peritoneal cavity of the guinea-pig one no longer finds free particles of myelin, as they are all englobed by the leucocytes. R.

Regenerative Processes of the Liver. — Pearce describes (*Journal of Medical Research*, July, 1906) the process of repair of local necroses of the liver produced in dogs by the injection of hæmagglutinative sera. The phenomenon is of special interest in that the lesions are caused by an agent reaching the liver through the circulation, and is therefore comparable to acute yellow atrophy and other toxic necroses in man. The first evidence of repair is the occurrence after thirty-eight hours of mitotic figures in the liver cells. At the end of the second day these have increased, and a considerable proliferation of endothelial cells has occurred in and about the necrotic areas. These latter tend to encapsule the necrotic cell fragments. During the following three or four days, while these processes advance, the necrosed tissue is largely replaced by granulation tissue. There is some evidence that quite small areas of necrosis, involving only a few cells, may be replaced by proliferation of liver cells, without the formation of connective tissue, but in all areas of appreciable size the latter is a prominent feature. Later, however, the connective tissue is, to a great extent, replaced by liver cells, only the coarse bands remaining. The great power of the liver cells to increase by indirect division is a striking feature throughout the whole process. Many multinuclear and giant liver cells are observed in the zone between the normal liver substance and the necrosed patches. New bile ducts aid, by a transformation of their cells into liver cells, in the restoration of the liver tissue. R.

Trypanosomiasis in Man and other Animals.—Tobey (*Journal of Medical Research*, July, 1906) gives the history of our knowledge of trypanosomiasis, and an enumeration and description of the various forms of trypanosomes, and the diseases they cause among different animals. (1) *Fishes.*—The list of fishes in which trypanosomes have been found is a long one, including the carp, the tench, the bream, the eel, the sole, the dog-fish, and the minnow. (2) *Amphibia.* Frogs are very subject to trypanosomiasis, various forms of the organism having been observed. (3) *Reptiles.* Trypanosomes have been seen in both snakes and turtles. (4) *Birds.* Many common birds are subject to trypanosomal infection—*e.g.*, blackbirds, robins, sparrows, pigeons. (5) *Mammals.* Rats in all parts of the world are found to be infected with the trypanosome first described by Lewis in 1877. Horses suffer from five well known trypanosomal diseases—nagana, surra, mal-de-caderas, dourine, and Gambian horse-sickness. Some of these diseases also

affect other mammals. Cattle in the Transvaal suffer from "galzeikte," a trypanosomal disease, which is not known to affect any other animal. In man, as is well known, sleeping sickness is due to a trypanosome. R.

Physiology of the Peritoneum. — Clairmont and Haberer ("Arch. für Klin. Chir.," Bd. 76, H. and L.) have made numerous experiments on the absorptive properties of the peritoneum and have arrived at some important results. The method of examination consisted in examining the urine at intervals after intra-peritoneal injections of potassium iodide. They found in the first place that the absorptive powers were unfavourably influenced by simple laparotomy and also by eventeration, the latter having a more marked effect than the former. Prolonged washing with warm physiological salt solution diminishes the unfavourable effect, and increase in the abdominal pressure or inflation with air has a similar beneficial effect. On the other hand absorption is much retarded during ordinary narcosis, and by morphine or physostigming injections. During the first stage of inflammation absorption is distinctly accelerated. Therapeutically their most important observation is the fact that washing out of the cavity is the most judicious prophylactic means at our disposal to ward off general peritonitis in operation cases, whether the peritoneum itself be normal or inflamed. M.

Congenital Laryngeal Atresia.—Frankenberger ("Virchow's Archiv." Bd. 182, H. 1), draws attention to the fact that congenital stenosis of the larynx has only rarely been described and that actual atresia is so rare as to be almost unknown. Hitherto four cases in all of the latter condition have been reported, and to this the author now adds a fifth. In the larynx of a still-born child he found on each side, in the place of the arytenoid cartilage, a large cartilaginous nodule standing out very prominently under the mucous membrane. The vocal cords were developed, but the rima glottidis was completely obliterated, so that it was impossible to enter the larynx even with the finest sound. The trachea itself, however, was patent. Histological examination did not reveal any trace of old inflammation. The epithelium was cylindrical and the mucous membrane normally developed. Mucous glands were absent at the actual site of adhesion, and in this place the blood-vessels were especially numerous. The actual binding tissue was partly connective and partly muscular in nature. M.

Influence of High Altitudes on General Nutrition.—Guillemard and Moog ("Compt. Rend. de l'Acad." T. 141, p. 843) have investigated the condition of their urine at Paris, Chamonix, the Grand Mulets, and at the summit of Mont Blanc. They found that the general quantity of the urine and also the mass of its ingredients were much reduced during their first few days at a high level; but that a gradual increase ensued, so that the normal was reached about the sixth to the eighth day. Both organic and inorganic constituents were retained, the latter in greater quantity than the former. There was no definite parallel between the total urea and total solids excreted, and the uric acid showed no characteristic change. Cryoscopic examination showed a lessened molecular concentration and the presence of intermediate metabolic products. M.

Parotid Secretion in Man. — Two cases of parotid fistula gave Zebrowski ("Pfluger's Archiv.," Bd. 110, H. 3 and 4, S. 105) the opportunity of studying the reaction of this gland to various food stuffs. After three months' study he has come to the conclusion that it is really irritating substances and the irritating qualities of substances which principally call forth the secretion. This leads the writer to deny to some extent Pawlow's doctrine, of conformity of quality and amount of secretion to the quality and quantity of food taken, but not *in toto*, for he finds that the alkalinity of the secretion becomes enhanced when acids are given and that the ferment strength becomes greater in proportion to the amount of organic substances in the food. He also finds that dryness of food leads to an increase in secretion, and that there is a considerable increase in quantity of saliva poured out, and a very considerable alteration in its properties corresponding to the quantity of the various foodstuffs administered. The alkalinity and ash content, the ferment power and the amount of organic material present in the saliva are directly related. M.

Digestion of Proteid in the Stomach. — Lobler has investigated this matter in dogs by making a duodenal fistula as near as possible to the pylorus, and introducing a metallic cannula into the intestine as described by Pawlow. When the preparations were complete 100 grammes of flesh were given to the dogs, and the appearance of acid juice in the cannula was awaited. As soon as the first drops appeared, the upper part of the intestine was severed from the duodenum, and a button was placed in the last named, so that all the stomach contents were discharged through the cannula. A portion of the digestive products from the stomach was also injected from time to time into the distal end of the severed intestine. The first point determined was that the discharge of the early digested products took place almost immediately after the exhibition of the food, and flowed out from the stomach in a thin fluid form. The periods of discharge followed rapidly, and were interrupted by regular reflex closures of the pylorus, each closure period of the pylorus tending to lengthen as digestion proceeded. Of the food given only 20 per cent, remained undissolved. The dissolved albumin consisted at the end of stomach digestion of 80 per cent. pepsine and 20 per cent. albumin; and of this between 20 per cent. and 30 per cent. was absorbed within the stomach itself. M.

Primary Sarcoma of the Spleen.—Daddi reports (*Rivista Critica di Clin. Med.*, 1905, No. 48) a case of primary sarcoma of the spleen which he considers of interest both from its rarity and from a diagnostic point of view. It occurred in a man æt. 64, whose illness began with sudden pain in the left hypochondrium, and a swelling was soon noticed in that position which was regarded as an enlarged spleen. The swelling persisted, the patient grew weak and emaciated and died about two months later with the symptoms of general peritonitis. The blood examination had shown diminition of hæmoglobin, diminution in the number of red cells, and a normal white cell content, except during the last few days, when there was a neutrophile leucocytosis accompanying the peritonitis. As a result of the blood-count, leukæmia and Hodgkins' disease were excluded during life, and so also was malaria, and inasmuch as the blood resembled what is found after extirpation of the spleen it was concluded that a malignant tumour was present destroying the function of that organ. At the autopsy a typical sarcoma of the spleen was found with secondary nodules in the stomach and intestinal walls. M.

Experimental Cirrhosis of the Liver. — Pearce has injected dogs (*Albany Med. Annals*, 1906) with the blood serum of rabbits, which had been previously subjected to repeated injections of red corpuscles obtained from dogs. When the serum was injected into the femoral vein or into the peritoneal cavity necrotic areas of smaller or larger extent were formed. Most of the animals experimented with died at once, but in the few that survived it was possible to observe that the necrotic areas gradually underwent regeneration. After some little time very numerous mitotic division figures were visible in the necrosed parts, or these parts were invaded and finally completely replaced by connective tissue. The final result after about thirty days was a general hardening of the liver with granulation of the surface, and with general cirrhosis. Pearce claims to have been the first to demonstrate liver cirrhoses produced in this manner and to have observed their development. The type of cirrhosis, however, is very different from that found in man. M.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

M.D. (Oxford).—With regard to your query re a small flat or rooms in West Central London we know that you will not get what you want under £100 or £130 per annum.

LEGISLATION ON ALCOHOL, DRUGS, &c.

VICTORIAN.—New regulations have just been passed by the Victoria Board of Health. One deals with the amount of alcohol contained in patent medicines, and the other prohibits the sale of preparations containing certain specified drugs, unless the presence of the same is notified on the label; preparations containing more than 10 per cent. of spirit are to be sold as alcoholic compounds. The regulations come into force on October 1, and are independent of the regulations imposed by the Federal Commerce Act.

DR. G. (Ramsay).—With regard to the relation between atmospheric conditions and the occurrence of cerebral hæmorrhage, temperature in itself has not been shown to exert any influence, though cases have been slightly in excess on days with a rising thermometer and increased atmospheric pressure.

LEGAL.—We hear the Mayor of Otley has supplanted the dirty covers of the Testament by celluloid ones, which can be easily washed after being kissed by witnesses.

"BY A PHYSICIAN."—You are quite right about the erroneous matter in some of the articles thus signed in the lay papers. They manage better in New York, where the medical portion of the journal is conducted by leading doctors, who write on questions which may advantageously be thought about by the laity.

DR. M. (Hampstead).—Such impostors are not rare in consulting rooms. They generally give the name of another doctor as reference. A good test is to say you will telephone to the one mentioned at once. In one instance this had the effect of making the man hurry out of the house.

Vacancies.

Royal Dental Hospital of London (School of Dental Surgery), Leicester Square, W.C.—Demonstrator of Practical Dental Surgery. Salary £100 per annum. Applications on or before Monday, September 24.

Egyptian Government.—Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year, with private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Egyptian Government.—Ministry of Education.—Medical Tutor and Registrar to Kasr-El-Ainy Hospital. Salary £400 a year. No private practice. Applications to the Director, School of Medicine, Cairo, Egypt.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary and House Governor.

Manchester University.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar.

Sussex County Hospital, Brighton.—House Surgeon. Salary £100 per annum, with board and residence in the hospital, with washing. Applications to the Secretary.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C. Founded 1804.—Senior House Surgeon. Salary £100 a year, with board and residence in the hospital. Applications to the Secretary.

Camberwell House Asylum.—Second Medical Assistant Officer. Salary £150 per annum, with board, apartments, and laundry. Applications to Medical Superintendent.

Royal Southern Hospital, Liverpool.—Resident Pathologist and Registrar. Salary £100 per annum, with board and residence. Applications to the Chairman of the Medical Board.

Kidderminster Infirmary and Children's Hospital.—House Surgeon. Salary £120 per annum. Applications to the Secretary.

City of Birmingham Asylum, Rubery Hill, near Birmingham.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Southwark Union, London.—Third Assistant Male Medical Officer at the Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Howard C. Jones, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.

Appointments.

ATKINSON, E. L., M.R.C.S., L.R.C.P., Senior Obstetric House Physician to St. Thomas's Hospital.

ATTLEE, CECIL K., M.R.C.S., L.R.C.P.Lond., House Physician at the Evelina Hospital for Sick Children.

BIRCH, CHARLES, M.R.C.S., L.R.C.P.Lond., Medical Officer to Claysmore School, Pangbourne, Berks.

BROWN, W. L., L.R.C.P., L.R.C.S.Edin., L.F.P. and S.Glas., D.T.M. Lond., Assistant Anæsthetist to the Central London Hospital.

CLARKSON, F., M.B., B.S.Durh., Special Department (Ear), to St. Thomas's Hospital.

COATS, GEORGE, M.D.Glas., F.R.C.S.Eng., Additional Ophthalmic Surgeon to the Out-patient Department at the Great Northern Central Hospital, London, N.

COX, R. J. H., M.B., B.S.Lond., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital.

CUNNINGHAM, N. R., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.

DICKSON, A. N., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.

DUNKLEY, E. V., M.B., B.S.Lond., M.R.C.S., L.R.C.P., House Physician to Out-patients to St. Thomas's Hospital.

ECKENSTEIN, K. E., M.R.C.S., L.R.C.P., Children's Surgical, to St. Thomas's Hospital.

EYRE, C. R. B., M.R.C.S., L.R.C.P., Junior Obstetric House Physician to St. Thomas's Hospital.

GAMLEN, R. L., B.A.Cantab., M.R.C.S., L.R.C.P., House Surgeon to Out-patients to St. Thomas's Hospital.

GOTZLEE, H. E., M.R.C.S., L.R.C.P., Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

GRAY, H. T., M.A., B.C.Cantab., M.R.C.S., L.R.C.P., Special Department (Throat), to St. Thomas's Hospital.

HEWETT, F. S., B.A.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital.

HOOKER, A. W., M.B., B.S.Lond., M.R.C.S., L.R.C.P., Junior Casualty to St. Thomas's Hospital.

HOWITT, A. B., M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital.

HOWARTH, W. G., M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital.

HUGHES, PERCY T., M.B., C.M.Edin., D.P.H., Medical Superintendent to the Worcester County Asylum, Barnsley Hall, Bromsgrove.

LEEDHAM-GREEN, CHARLES, M.B.Birm., F.R.C.S.Eng., Honorary Surgeon to the Queen's Hospital, Birmingham.

MACDONALD, S. G., B.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., House Surgeon to Out-Patients, St. Thomas's Hospital.

MACLEAN, I. C., M.R.C.S., L.R.C.P., Children's Surgical, to St. Thomas's Hospital.

MACLEAN, I. C., M.R.C.S., L.R.C.P., Electrical Department (X-Ray Department), to St. Thomas's Hospital.

NORBURY, L. E. C., M.B., B.S.Lond., M.R.C.S., L.R.C.P., Senior Casualty Officer to St. Thomas's Hospital.

PAGE, C. M., M.B., B.S.Lond., M.R.C.S., L.R.C.P., House Surgeon to Out-Patients to St. Thomas's Hospital.

PHILPOT, H. A., B.A.Oxon., M.R.C.S., L.R.C.P., House Physician to Out-patients to St. Thomas's Hospital.

SANKEY, W. O., M.R.C.S., L.R.C.P., House Physician to Out-patients to St. Thomas's Hospital.

SINGTON, H. S., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.

SQUIRES, H. C., M.A., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.

STEEL, R., L.R.C.P., and S.Edin., District Medical Officer of the Auckland Union.

TREVES, F. B., B.A.Cantab., M.R.C.S., L.R.C.P., Special Department (Throat), to St. Thomas's Hospital.

WALLACE, J., B.A.Oxon., M.R.C.S., L.R.C.P., Special Department (Skin), to St. Thomas's Hospital.

WARD, W. C. A., M.R.C.S., L.R.C.P., Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

WEBB, G. L., B.A., B.C.Cantab., M.R.C.S., L.R.C.P., Special Department (Skin), to St. Thomas's Hospital.

WHITEHOUSE, H. B., M.B., B.S.Lond., M.R.C.S., L.R.C.P., House Surgeon to Out-patients to St. Thomas's Hospital.

WILSON, A. G., M.B., F.R.C.S.Eng., Certifying Factory Surgeon for the West Sheffield District, co. York.

Births.

ARMSON.—On August 18th, at The Moat, Yoxall, Burton-on-Trent, the wife of Frank G. Armson, M.R.C.S., L.R.C.P., of a son.

BLOMFIELD.—On August 27th, at 211, Queen's Road, Peckham, the wife of Alfred Blomfield, M.R.C.S., L.R.C.P., of a daughter.

BOWER.—On August 28th, at Viewfield, Stretton, near Warrington, the wife of H. E. Bower, M.D., of a daughter.

BUTTERWORTH.—On August 29th, at 6, The Crescent, Wisbech, Gertrude Helen, the wife of Rupert Butterworth, B.A., M.B., B.C., Cantab., of a daughter.

PEDLEY.—On August 24th, at Wave Crest, Whitstable, the wife of S. E. Pedley, M.R.C.S., L.R.C.P., L.D.S., of Camberwell, and Regent House, Oxford Circus, London, of a son.

ROBERTSON.—On August 30th, at Althorpe, nr. Doncaster, the wife of J. F. Robertson, M.R.C.S., of a son.

Marriages.

KILROY—MACLAREN.—On September 1st, at St. Michael's Church, Camberley, Willie Dickson, son of the late Lieut.-Colonel Philip Le Feuvre Kilroy, R.A.M.C., to Edith Mary, daughter of the late Francis Blayney Maclaren, M.I.C.E., Suptg. Engr. Indian Public Works Department.

Deaths.

WHITE.—On August 26th, at Victoria Hospital, Folkestone, Richard Dormer White, M.A., M.D., Univ. Dublin, Dep. Insp.-Gen. of Hospitals and Fleets Royal Navy, aged 61.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, SEPTEMBER 12, 1906. No. 11.

NOTES AND COMMENTS.

Rocks ahead in Practice.

There are many rocks ahead in the career that awaits the student who has crossed the bar of medical qualification. To paint the canvas as if it were a paradise free from care and trouble would be to produce a false picture. Sooth to say, the general practitioner who has to live by his profession will find that the financial question is always with him. In his earlier days it often becomes a hard matter to struggle on into the smoother waters of competency. Rarely is it given to him to make what business men would regard as a moderate fortune. Yet it can hardly be denied that medicine is one of the most learned and necessary of all the professions. Why, then, should it be cursed with the dead-weight of ever-narrowing income? The answer is complex. First of all, medical men have not learnt to protect their interests collectively, especially by adequate Parliamentary representation. Then there is the want of regulation as regards hospital patients, whereby many persons who can afford to pay fees are treated gratuitously. Again, there is the flood of unqualified practice and arrant quackery which swamps the efforts of the legitimate practitioner with ever-increasing volume. The student will do well to keep these facts before him, for one day they will profoundly affect his professional life.

The Quack Question.

For many years the MEDICAL PRESS AND CIRCULAR has been the bitter foe of quacks and quackery, and unqualified practice that stalks with brazen impudence through the highways and the byways of the whole kingdom. No cottage is too poor, no palace too rich to be safe from invasion by the charlatan who floods the country with pamphlets and the newspapers with advertisements, in which he claims to cure cancer, blindness, locomotor ataxy, epilepsy, chronic kidney and liver diseases, and, in short, every malady known to medical science, whether curable or incurable. Meanwhile the Legislature, which has decreed stringent laws for the education, the qualification, and the control of medical men, folds its hands and permits this wholesale illegitimate practice of medicine by unqualified persons. As a rule the police are equally supine. Of late, however, it is gratifying to note that they have prosecuted and sent to hard labour several notorious persons. Their ground of action has been clear and simple. They have brought a charge of obtaining money under false pretences, and have had no difficulty in proving their case up to the hilt. Should the police of London, Dublin, and other great cities wake up to a sense of their responsibilities, they would find their hands full for some time to come. The benefit of some such concerted action would be of incalculable value, not less to the community than to the medical profession.

How the Charlatan Robs and Slays.

For the charlatan is as multifarious as he is extortionate and callous. The average bonesetter is a perfect specimen of the class. Without a vestige of anatomical or surgical knowledge, he professes to cure all kinds of bodily deformities and injuries, the knowledge of which can only be acquired medically by a lifetime of devotion and careful training and study. Yet some bonesetters, mere ignorant colliers and the like, are permitted to conduct large practices. Needless to say, every penny they take in fees is deducted from the legitimate income of properly qualified medical men, to say nothing of the untold suffering and misery that is inflicted upon their misguided victims. A similar track of evils marks the disastrous path of other charlatans. Their list is legion: skin and nerve specialists, electricians, dermo-featural specialists, curers of deafness, blindness, paralysis, kidney diseases, and a host in other fields of irregular practice. Now, if the police chose to prosecute, there can be little doubt that even under the present defective Medical Acts the career of many of these quacks could be cut short once and for all. Where, then, are the police, and why is the British public defrauded in this bare-faced fashion? When the police prosecute they almost invariably get a conviction, yet to-day there are many worthless persons preying on the misfortunes of the public.

Police and Parliament.

The fact appears to be that no comprehensive system of police administration exists so far as prosecution of public frauds is concerned. Parliament is content to enter laws upon the Statute Book and leave their administration to fate. In the case of the medical profession, care has been taken to secure the proper persons in public posts where a qualified medical man is required. The weak point is that equal care has not been taken to exclude the unqualified medical pretender. Such is the loose wording of the Medical Acts that the quack cannot be successfully prosecuted unless he assume a title actually named in the Acts. The logical attitude of the law would be to declare illegal all actions appertaining to medical practice if performed by persons not possessing a duly recognised qualification. Precisely the same line of argument applies to police and to legislature as regards patent medicines. The false pretences of the nostrum vendor are no less obvious than those of the quack: they are just as disastrous to the community. Last, but not least, they depend for their existence upon the complacent indulgence of the newspapers which insert the advertisements of quacks and quackery.

The Lay Press and Quackery.

Newspaper proprietors generally—there is no object in mincing matters—are answerable for this enormous mass of quackery that is preying upon the community. It is saddening to reflect that a body of men, professing and inheriting the noble traditions of the British Press, can foster the existence of so dishonourable a traffic simply because of the income they derive therefrom. As a mere matter of deduction, if the police can send to hard labour a quack, they are entitled to prosecute the newspapers that have inserted his obviously fraudulent advertisements. Fancy the owners of the *Times*, or the *Standard*, or any other of the great daily newspapers—for none is free of the taint—being solemnly prosecuted for conspiracy to defraud by advertising Smith's cancer cure, or Brown's sovereign remedy for epilepsy, or Jones's specific for Bright's disease. All such medicines can be proved worthless by simple chemical analysis. Certain religious journals are notorious for the number and the reckless variety admitted to their columns. In a word, it is clear that it is to the monetary interest of the newspapers to traffic in patent medicines and in quackery. If the newspaper press were to unite with the police in the suppression of swindling quack advertisements this nefarious traffic would wither and fade within a week like grass cast into the oven. The newspapers, however, as a rule subordinate the welfare of the community to their own sordid interests.

"Truth" and Quackery.

Even those journals that set up the highest ideals seem unable to purge themselves from the taint. Take, for example, *Truth*, which is commonly looked upon as a great bulwark of society, so far as concerns exposure of shams and frauds, and which alone amongst lay journals has continuously waged war against fraudulent quacks. Yet there are spots even on this sun. Elsewhere in our present issue we print a letter from a correspondent drawing attention to a whole string of medical advertisements appearing in a single issue of *Truth*. We confess we had not previously scrutinised the columns of our contemporary for that class of announcement feeling sure they could not be found there; and we were astonished by an outburst of indignation when some weeks ago we mildly ridiculed the advertisement of the "double-chin cure," which had casually caught our eye. The value of the censorship of *Truth* over quacks and quackery, and its denunciations of the whole of the lay press for their laxity would, to put it mildly, be vastly strengthened were a closer criticism exercised over the advertisements admitted to its own columns. If *Truth* desires to co-operate with effect in the movement to obtain a Royal Commission, its position will evidently need some alteration. We confess we do not at present clearly understand it.

The "Medical Press and Circular" and Quackery.

Amongst the medical journals the MEDICAL PRESS AND CIRCULAR can claim to be the only one that has consistently followed up this subject. In season and out of season we have insisted upon the damage inflicted upon the community by the huge abuses of charlatanism. The task is a thankless one so far as the public is concerned, but we are glad to believe that our efforts are appreciated by the medical profession. A few weeks since we urged the desirability of obtaining a Royal Commission to inquire into the whole subject of quacks and quackery. That suggestion we purpose in future to make one of the chief planks in our platform. With that end in view we should be happy to open a fund for the suppression of quackery and the advocacy of a Royal Commission. Some valuable work has been done by way of repressing the evil by the Medical Defence Associations, especially by the oldest of them, the Medical Defence Union. We should earnestly advise all members of the medical profession to regard it as a matter of expediency to join one of these societies directly he secures his qualification to practise.

The Defence Unions.

For the day of trial may come to the best of us, and then it is well to have at one's back the machinery of a strong and experienced Defence Union. There is no very apparent reason why medical students should not be admitted to those societies: perhaps the point may be considered by their councils, which have shown in many directions that they are guided by a most progressive and energetic policy. Possibly they may contain the germ of future indirect protection of our profession by extending their present sphere of activity in the prosecution of quacks. That function should, in the ordinary course of things, devolve upon the General Medical Council, but that body partakes of the general topsy-turveydom of medical legislation, and has neither the will nor the power to suppress illegal medical practice. Another body that the student will do well to regard with respect from his earliest entrance to the profession is the Medical Sickness, Accident, and Insurance Society. It was founded by medical men for the benefit of the profession, and has become a splendid and assured success. It is possible that in this case also the suggestion to include medical students amongst its members might be favourably regarded.

Advice to the Student.

There are certain things that the student of medicine will do well to keep in his mind from the outset of his professional career. In after life, at any rate, he will find that the keen delights of scientific research and of philosophical method have to become subservient to the necessity of making a livelihood. So far as the latter point is concerned, he will find himself seriously handicapped in various ways. One thing he can do while at hospital is to satisfy himself of the reality of the abuse of medical charities by persons who can afford to pay outside practitioners. Let him bear in mind that every time he ministers to such a person he is depriving some practitioner outside the walls of the hospital of a legitimate fee even if it be no more than the shilling or eighteenpence to which want of organisation and adequate defence has reduced the general practitioner. It may not be possible for the student to decline to treat a well-to-do patient. Such a step is likely to bring him into disfavour with the hospital authorities, who do not care to discourage this increase of patients. With the Managing Committee and the Secretary, large numbers indicate popularity, and score with the public. They care not one jot for the outside medical man, who has to look after his own interests—if he can.

Further Advice.

These may sound hard words, but their truth has to be learnt sooner or later by an overwhelming proportion of the rank and file of the medical profession. Happily, there are signs on the horizon that the profession intends seriously to grapple with this unfair hospital competition.

The student will also do well to keep an eye on the evils wrought by quacks and quack medicines. The money obtained by that means from the community is to a great extent diverted from the income of medical men. There is little comfort to the struggling practitioner to remind him that in the long run the use of patent medicines brings many persons back to his consulting rooms. The student had better grasp this fact early in his career, namely, that in most cases it is possible to secure a moderate competency in practice, rarely more, and that in most instances the consciousness of a life devoted to a high and honourable calling will be his chief reward. That reflection has been the mainstay of many a man of culture and noble purpose, condemned to live through days of prolonged financial narrowness. There is no need, however, as we have more than hinted, why the medical man of the future should not unite noble aims with the possession of adequate income, provided he can organise sufficiently to insist upon the recognition of his just professional rights.

M. Tanqueray again.

A further letter from Tanqueray, of Paris, to whose solicitude to provide free portraits for the medical profession we have already referred, has been received by the member of our staff who foolishly sent a photograph for reproduction in accordance with Tanqueray's original and enticing offer. As our previous note on this subject proved interesting to some of our readers, the contents of the latest, and we believe the last, communication from Tanqueray, may also be of interest. He commences by calling attention to the beauty of the portrait which awaits its owner in his studio, and explains that it requires careful package. He then expresses his willingness to send it "free of all expense" for the sum of eight shillings, and, in addition, to present the recipient with a "handsome detective camera" with developing and printing outfit complete. It may be remembered that the original offer was to send the portrait for ten shillings, which sum would cover package and carriage. Now, for eight shillings, one receives not only the portrait, but also the photographic equipment "free of all expense." Whether the latter cryptic phrase means "carriage paid" we leave our readers to imagine. In view of Dr. Falls' experience, as recorded in the MEDICAL PRESS AND CIRCULAR for August 29, we have no doubt on the subject. Tanqueray ends his last letter by saying that if he does not hear within thirty days, he will assume that "neither your portrait nor your photograph are of any interest to you"—in other words, a plain threat that if he is not paid he will not return the original photograph. We further note that, whereas on the letter addressed to and retained by the customer, the offer is to send the portrait "free of all expense," on the order-form, *which is to be returned to Paris* with the money, the statement is made that the eight shillings prepays all charges of boxing, packing and carriage. A very ingenious trick!

SIR FRANCIS LAKING, Bart., Physician in Ordinary to His Majesty the King, was conveyed in a special train from Abergeldie to Aberdeen yesterday, and is now in a private nursing home. He was taken ill at Abergeldie, and is not progressing favourably.

PERSONAL.

THE Huxley Lecture will be delivered at Charing Cross Hospital Medical School by Professor Ivan Petrovitsch Pawlow, Professor of Physiology, University of St. Petersburg, on Monday, October 1st, 1906, at 4 p.m.

THE first report of the expedition to the Amazon, organised by the Liverpool School of Tropical Medicine has been issued by Dr. H. Wolferstan Thomas.

PROF. CLIFFORD ALLBUTT, F.R.S., will deliver an address at the opening of the Winter Session at Guy's Hospital, on October 1st.

MR. PRIDGIN TEALE, F.R.S., will open the Session at King's College Hospital with an introductory lecture on October 2nd, whilst Prof. R. Godlee will re-open University College Hospital.

ON October 1st the Dean of St. Mary's Hospital, Dr. W. H. Alcock, will deliver the inaugural address. On the same date Dr. H. Campbell Thomson will perform the same function at Middlesex Hospital, and Dr. de Havilland Hall, at Westminster.

THE Winter Session at the London Hospital will be opened by a dinner under the presidency of Mr. John Holroyde, of Rochester.

PROF. BYERS will open the Session at the London School of Medicine for Women on October 1st, and on the same date Colonel Kenneth Macleod, I.M.S., will deliver the inaugural address at the London School of Tropical Medicine.

PRINCESS HENRY OF BATTENBERG last week paid a visit to the Royal National Hospital for Consumption at Ventnor, after opening the fête and bazaar, for the purpose of completing the fund of £1,000 for the endowment of a bed in memory of Dr. Sinclair Coghill, the late senior physician.

A MARIENBAD correspondent writes:—"The King's departure for England signalizes the break-up of a season which, apart from the painful sensation caused by the death of Lady Campbell-Bannerman, has been the most enjoyable ever experienced here. There can be little doubt that, when the King arrives home, it will be agreed that seldom has he appeared in better health and spirits as the result of a Continental holiday. I know that Dr. Ott, under whose care the King has been taking the cure, is very well satisfied with the progress made by his patient. Several sittings have been given by His Majesty to Herr Gurschner, who is engaged on a model of the King's features for the monument to be erected in the town. A further item of Marienbad news is that some of the scandal-mongers who had been busy with the name of a young and beautiful Society dame, have received a sharp rebuff from an unexpected quarter."

I LEARN that Sir Frederick Treves, who has been in attendance on Queen Alexandra throughout her absence from England, is returning specially from Copenhagen in order to arrive in London in time to have an interview with the King before His Majesty's departure for Doncaster. The King is naturally very anxious to learn from Sir Frederick's own lips the real state of Her Majesty's health, and to discuss whether it would be better that her journey from Copenhagen to Scotland, later in the month, should be made entirely by sea, or broken by a rest in London,

EDUCATIONAL SUMMARY FOR 1906-7.

INTRODUCTORY REMARKS.

THERE are two classes of people for whom a Students' number is primarily intended, namely, those who may be thinking of taking up Medicine as a career, and those who have already decided to do so and who wish for guidance as to the school they should choose, and the line of professional activity they should adopt in the future. To the former class we unhesitatingly say, "Take full time and make every possible inquiry before arriving at your decision, remembering that if a man hesitates about choosing Medicine for a career, the strong probabilities are that he is not suited by nature for its pursuit." Medicine as a means of livelihood demands so much self-sacrifice and so much really hard work that unless a man is attuned by nature to the peculiar circumstances attending its practice it is far better for him, and certainly far better for the public, that he should find some more congenial sphere for his talents. The world is full of minor tragedies, and of these misapplied lives are by no means the least; there are many medical men in practice to-day whose minds fluctuate so much between regret for the past and anxiety for the future that they are unable to do justice to the daily round of duty. Such men might have made admirable soldiers, bankers, or colonists, but obviously they do not make the best doctors, even if they make good doctors at all. Therefore it cannot be too strongly impressed on those whose thoughts turn towards Medicine, that they should examine themselves as to whether they are worthy of the aim. But Medicine with all its trials and responsibilities has pleasures and privileges all its own, and there are not a few who love their work and their patients and their lives with a fondness that could be evoked by no other calling. Such men are not necessarily intellectual giants nor the most eminent practisers of their art, but they have that within them which vibrates sympathetically with the note struck by their surroundings; they give and receive pleasure with equal facility.

Happiness in the practice of Medicine, indeed, may be said to be a question of aim and a question of disposition. It may be taken for granted that pre-eminence in the State and great wealth will never come to the doctor, however intellectual, industrious, and successful he may be; if a man be possessed of such qualities, and wishes to make the best of them, he had better not adopt Medicine for his profession. The law, the church, the army and navy will all bring him distinction, a title, and the two former, at least, wealth. He will find nothing of the sort in the medical profession unless he become a Court doctor, and "the fashion," when he may be made a baronet and earn a fair income for a few years. The type of man who aims at these distinctions, however, had better choose some other career, for not only is the conventional consideration accorded to the leaders of the profession of Medicine far below that accorded to a judge, a general, or a wealthy brewer, but their work is far harder. If, on the other hand, a man endowed with good talents and resolution wishes to use these not solely for his own advancement and comfort, but would like them to be of service to his fellows, he will probably find in the practice of Medicine a wider field for their application and a more tangible amount of good to be done than in any other path in life. Success in Medicine, in fact, is not capable of being gauged accurately by the bank-ledger and precedence at Court, because the work of the doctor consists, or should consist, in giving as much as in taking, and the doctor's pleasure is, or should be, as great in seeing his patients in good health as in being able to provide the amenities of life for his own family. Medical practice must always be regarded as a form of altruism, out of which if the doctor saves sufficient to keep himself going, he is abundantly content. As men in other walks of life regard their business or calling as a means of livelihood, and only consent to give away of their surplus, they are generally unable to see things from the doctor's standpoint, and medical men are consequently written down as "unbusinesslike." And this is perfectly true, for the aims of "business" are purely selfish, whilst those of medicine are as much unselfish as selfish. The aspirant after medical skill and knowledge cannot be given too clearly to understand that success in Medicine is different to success in other professions, and that the medical man who gains worldly applause but is not rewarded by the happiness that comes from otherworldliness is a failure, whilst an obscure practitioner who mixes his pills with kindness and receives gratitude with his humble fees is a success. The difference between the practice of Medicine and the pursuit of any other calling, then, is a difference of ideal, and unless a man is willing, nay, eager, to subordinate his own advantage to the requirements of the medical ideal, he will never be content with the profession as a sphere for advancement. If, however, he enters its portals in a spirit of devotion and self-subordination, he will find greater opportunities for the exhibition of these virtues than is generally appreciated.

CHOICE OF A SCHOOL.

The decision to study Medicine once made, no reasonable person can grumble at the variety of schools provided in the British Isles. Some twenty centres of medical instruction at present exist, and most of them embrace so many individual colleges and hospitals that the would-be student who tries impartially to balance the advantages presented by them all is likely to find himself in an agony of indecision. Some of the centres are complete and self-contained. A man has only to enter, pay his fees, pass his exams, and emerge on the Medical Register with the automatic precision of an American sausage-manufactory. Others cater only for the preliminary education of the students, and others again only for those who would complete their course. Some give a degree, others a qualification, and still others refer those who study with them to a diploma-granting corporation. Some have large hospitals and few students; others small hospitals and many students; some rely on the reputation their teachers have gained as practitioners; others on the quality of instruction provided by more obscure individuals; some are possessed of influence and prestige; others are struggling to make a name. The only quality they have in common seems to be a desire for students, so that a man is likely to find himself welcome wherever he goes. To attempt specific guidance in the maze of these competing attractions is a thankless task. Full particulars of the advantages provided by all will be found in the pages of this number.

CHOICE OF QUALIFICATIONS.

It may be safely asserted that a man who possesses a university degree has a distinct pull over a man who possesses a diploma only. The only exception is when purely surgical practice is aimed at, and the aspirant is armed with the fellowship of one of the Colleges of Surgeons. Even then the addition of M.B. to his qualifications will, *cæteris paribus*, be found helpful. Many men enter at a medical school with no clear idea of what they are in for, and too late they realise that they have trodden the path which leads only to a diploma, and which will land them in a disadvantageous position as compared with their degree-possessing brethren. The best universities, generally speaking, provide the stiffest examinations, and their degrees naturally confer the greatest *éclat* on those who hold them, but in these days of competition it is not difficult for a man who wishes to be less severely tested to find universities who give their M.B. for work of no higher standard than is rewarded with a diploma only in other centres.

COURSE OF STUDY.

Five years' study is now obligatory in all schools thanks to the efforts of the General Medical Council, but the man who completes all that is required of him in that time and finds himself fully qualified at the end is a *rara avis*. Seven years are found to be about the average for men of all capacities, and parents of limited means and guardians who wish to see their wards self-supporting would do well to pay attention to this fact. As legal qualification does not necessarily connote more than the potentiality to earn an income, expense cannot be considered at an end when the diploma is framed and displayed to admiring friends.

CHOICE OF A CAREER.

The future of a medical man once he is qualified will depend on his tastes, means, influence, and ability. The majority of men naturally go into general practice, the locality in which they settle and the class of practice they obtain being determined by personal connection or financial resources. A man of small means will settle in the neighbourhood of the poor who pay very small fees, whilst a man who is well off will take a good house in a fashionable quarter and cater for the rich and well-to-do who pay proportionately more. For those who are averse from private practice there are the services, the Army, Navy, West African, Colonial, and Indian Medical, in all of which pay, prospects and status have improved of late years; the various county asylums, each of which maintains a small resident medical staff; the poor-law infirmaries and fever hospitals, in both of which pay is low and prospects poor; the health departments of the municipalities and counties, in which a man who is contented with a few hundreds a year may, after some years of waiting, possibly acquire them; and various minor services, such as the prisons, which offer but little inducement to men of enterprise and energy. Consulting and special practice will come to a few men if they are successful in getting on the staff of a large hospital and have a sufficient income to support a more or less pretentious establishment for ten, fifteen, or twenty years.

SUMMARY.

Generally it may be said, then, that Medicine offers to its followers a career of great usefulness, and for those who have good health and devotion of character a life that will afford many peculiar pleasures. There is no opening in it for the idle, wanton and dissolute, and as everything depends on personal exertion the delicate will find their health an insuperable handicap. For men of good ability and merit, a competency is attainable, and there is always room at the top.

THE ENGLISH UNIVERSITIES.

THE English Universities are eight in number, *viz.*, Oxford, Cambridge, London, the Victoria, Durham, Liverpool, Leeds, and Birmingham. The choice of a University is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial universities.

OXFORD.

There are two degrees in medicine, B.M. and D.M., and two degrees in surgery, B.Ch. and M.Ch. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the second (B.M.) examination. Graduates in Arts, B.A., are alone eligible for these degrees. In order to obtain the degrees of B.M. and B.Ch., the following examinations must be passed :—1. Preliminary : Subjects :—Physics, chemistry, zoology, and botany. 2. Professional (*a*) First examination (held twice a year): Subjects :—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy; Materia medica with pharmacy. (*b*) Second examination : Subjects :—Medicine, surgery, midwifery, pathology, forensic medicine with hygiene. The approximate dates of the examinations are as follow : —Preliminaries:—Physics, chemistry, and botany, December and June; Zoology, March and June; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University who have entered on their thirty-ninth term on their presenting a dissertation approved of by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June.

The First examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be offered and passed together.

In the Second examination candidates are allowed to present themselves in pathology, and also in forensic medicine at separate examinations at any time after the First examination has been passed; but no candidate is permitted to enter for the examinations in medicine, surgery, and midwifery until he has attained the twenty-fourth term from his matriculation—*i.e.*, six years.

Diploma in Public Health.—The examination for the Diploma is held about the end of November in each year, and is open to any registered medical practitioner, whether he be a graduate of the University of Oxford or not. It is conducted according to the statutes and regulations of the University, and these have been framed so as to be consonant with the Resolutions and rules adopted by the General Medical Council for Diplomas in Public Health.

The examination consists of two parts. In the first of these candidates are required to exhibit a knowledge of chemistry and physics in the relations of these sciences to Public Health. In the second part of the Examination the candidate is examined in the subjects of general hygiene and of pathology in its bearings on Public Health. In all the subjects the Examination is partly practical. Candidates may offer themselves for the two parts of the examination on the same occasion or on different occasions; but their admission to the second part is contingent on their having already satisfied the examiners in the first part.

Candidates who desire to prepare for the examination within the University will be afforded facilities for doing so in the laboratories of the scientific departments concerned with the subjects of examination; and arrangements can also be made for candidates to acquire a practical knowledge of the duties of Public Health administration under the supervision of the Medical Officer of Health for the City of Oxford. Information on these points may be obtained by application to the Regius Professor of Medicine, University Museum, Oxford.

CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry and physics, and (2) biology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first and the third examinations are divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the students are divided into "Internal" and "External" An internal student is one who has matriculated at the University and is studying in a school approved by that body, or under the teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat in their application to the two groups of students. We only propose to deal with them as they affect *internal* students, since the special information required by the others had best be obtained direct from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least three years have elapsed since matriculation or other examination entitling to registration as a medical student.*

The Matriculation Examination takes place thrice yearly—in January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 16th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which *must* be English and elementary mathematics. The other three (one of them a language) may be selected from the following:—Latin, Greek, French, German, Arabic,* Sanscrit,* Spanish,* Portuguese,* Italian,* Hebrew,* Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced than in the compulsory examination), Elementary Mechanics, Elementary Chemistry, Elementary Biology (Botany), Elementary Biology (Zoology),* Elementary Physics, Heat, Light, and Sound, Electricity, and Magnetism. Candidates who desire to be examined in the subjects against which an asterisk is affixed must give at least two months' notice.

The Preliminary Scientific Examination will take place twice in each year, in January and July. It will consist of papers on inorganic chemistry, biology, and physics, and there will be a practical examination in each subject. Examiners will also be at liberty to test candidates *viva voce*. A student may present himself for examination in each of the three subjects, separately or in all at the same time. Part I. of this examination includes papers in inorganic chemistry, physics, and biology, with practical examinations; Part II. is an examination in organic chemistry. Six months must elapse after passing Part I.

The Intermediate Examination in Medicine will take place twice a year, January and July. Candidates must have passed the Preliminary Scientific Examination at least two years previously. The subjects of examination are Anatomy, Physiology and Histology, and Pharmacology, including Materia Medica. Candidates who have failed in one subject only at this examination may offer themselves for re-examination in that subject, if permitted to do so by the

* May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment of £2; Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have passed all the examinations required for a degree in those Universities also women who have obtained Tripos certificates granted by the University of Cambridge, and women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations at Oxford, they have passed the Second Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who hold the Scotch School Leaving Certificate, having passed on one and the same occasion, in the Higher or Honours Grade in all the subjects required by the regulations for the Matriculation Examination.

examiners. Three scholarships, one of the value of £40 in Anatomy, another of the same amount in Physiology, and one of £30 in Pharmacology may be awarded by the examiners to any candidate who has passed the whole of the examination at one time.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any centre must give notice upon their forms of entry to the Principal of the University. Besides the University fee a fee usually varying from £1 to £3 is charged by the local authorities and must be paid *at the local centre* before the commencement of the examination.

The Final M.B., B.S., Examination will take place twice a year, in October and May. No candidate will be admitted to this examination unless he has completed the course of study prescribed in the schedule or in less than two academic years from the date of passing the Intermediate Examination in anatomy and physiology.

The subjects of the examination are Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, and Midwifery and Diseases of Women. The subjects may be divided into two groups, one of which shall comprise Medicine, Pathology, Forensic Medicine and Hygiene; and the other Surgery, Midwifery and Diseases of Women. Either group may be taken first at the option of the candidate, or the groups may be taken together.

Only candidates who show a competent knowledge of all the subjects comprising a group will be passed. The examiners will be empowered to recommend the award of a University Medal to the candidate who has most distinguished himself in the whole examination.

Doctor of Medicine.—The examination for the degree of Doctor of Medicine will be held twice in each year, in December and July. Every candidate must have passed the examination for the M.B., B.S., of this University. Candidates may present themselves for examination in one of the following branches: (1) Medicine, (2) Pathology, (3) Mental Diseases, (4) Midwifery and Diseases of Women, (5) State Medicine: and if they wish, may pass also in another branch at a subsequent examination. Candidates for Branches 1 to 4 who have taken honours at the M.B., B.S. examination in the subject in which they present themselves for the M.D. degree, or who, subsequently to taking the M.B., B.S., have conducted a piece of original work approved for the purpose by the University, or have had special experience approved by the University, may present themselves for the M.D. examination one year after taking their Bachelor's degree. Other candidates must show that they have taken the degree of M.B., B.S., not less than two years previously; and as regards candidates in Branches 1 to 4, that subsequently to taking that degree they have held for at least six months a resident or non-resident medical hospital appointment, or that they have been in qualified practice for not less than five years, while candidates in Branches 2 and 3 must show that they have held in the one case a pathological and in the other an asylum appointment. In each branch there will be (1) two papers on the special subject of the branch; (2) a clinical examination; (3) an essay to be written on one of two given subjects connected with the branch. In Branch 1 there will also be a paper on pathology, and in Branches 2, 3, and 4 a paper in medicine, while in Branch 2 a laboratory examination will be substituted for the Clinical Examination held in the other branches.

Candidates in Branch 5 (State Medicine) must show that they have taken the degrees M.B., B.S. not less than two years previously, and that subsequently to taking those degrees they have had (1) six months' practical instruction in an approved laboratory; (2) six months' practical instruction from a medical officer of health, of which three must not coincide with the laboratory work, and three months' practice at a hospital for infectious diseases. The interval between passing the M.B., B.S. and proceeding to the M.D. State Medicine may be reduced to one year, subject to conditions corresponding to those affecting Branches 1, 2, 3, and 4.

Master of Surgery.—The examination for the degree of Master in Surgery will take place twice in each year, commencing on the same dates as the foregoing, and the general regulations already quoted with regard to the M.D. will practically apply to it, surgery being substituted for medicine. The examination will consist of (1) two papers on surgery (one of which may be a case for commentary); (2) an essay to be written on one of two subjects which may be selected from any branch of surgery; (3) two papers on surgical pathology and surgical anatomy; (4) a clinical examination; (5) operations on the dead body; (6) a *viva voce* at the discretion of the examiners. Competent knowledge in every subject of the examination must be shown in order to pass.

For the M.S. degree and all branches of the M.D. a candidate is at liberty to forward a thesis or copies of published works embodying the result of independent research in the subject in which he presents himself for a degree and also any printed contributions to the advancement of professional knowledge published either separately or conjointly. If the examiners consider such thesis or works of sufficient merit they are empowered to exempt a candidate partly or entirely from examination in the subject to which such work refers. They also have power to award a University Medal to the candidate who at the examination in any branch passes with most distinction.

Fees.—For Matriculation, £2 for each entry. Preliminary Scientific Examination.—Part I: £5 for each entry to the whole examination, and £2 for each subject when less than the whole examination is taken at one time. Part II.: No fee for first entry, £2 for each subsequent one. Intermediate Examination.—£10 for each entry to the whole examination, and £5 for re-examination in one subject. M.B. B.S. Examination.—£10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations.—£20 for each entry.

This University has established centres for preliminary and intermediate studies at University and King's Colleges, and students who purpose taking the London degree should make themselves acquainted with the details attached to external and internal students. Information on these points may be had of the Academic Registrar, University of London, South Kensington.

UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, *viz.*, the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt

from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must present an essay which has been prepared entirely by himself, and which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1905-6.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

Attached to this University for the acquirement of medical study and hospital practice, is the Royal Infirmary, a very commodious and ornate building, with 280 beds. Pathological demonstrations are given as opportunity offers. A new wing has been added to the College of Medicine to accommodate the departments of physiology and bacteriology. It also contains students' union rooms and gymnasium.

The New Royal Victoria Infirmary, containing 450 beds, has recently been opened by H.M. the King. In the new infirmary adequate accommodation will be provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to the students, some carrying with them an honorarium, whilst the scholarships available are numerous and of considerable value.

Fees.—(*a*) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. (*b*) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; one year, twelve guineas composition fee in one payment, twenty-five guineas; or by three instalments at the commencement of the sessional year, *viz.*, first year, 12 guineas: second year, ten guineas; third year, six guineas; or by two instalments, *viz.*, first year, fourteen guineas; second year, twelve guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

MANCHESTER UNIVERSITY.

Candidates for degrees in medicine and surgery must attend classes in the University during at least two years.

The degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for Degrees in medicine and surgery are required to pass the Matriculation Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Matriculation Examination are—1, Latin; 2, mathematics; 3, mechanics; 4, English and history; 5, one of the following:—(*a*) French; (*b*) German; (*c*) Greek; (*d*) Italian; (*e*) Spanish; (*f*) any other modern language, permission to present which has been obtained from the Joint Matriculation Board. Notice of intention to present either Italian or Spanish must be given to the Secretary, Joint Matriculation Board, Manchester, before March 1st in each year.

Before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities. All candidates for these Degrees must pass three examinations, and must have attended courses of both lectures and laboratory work.

The final examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B., or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. Degrees can be obtained on application to the Registrar.

Fees.—Matriculation examination, £2. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Final Examination, and for the examination for the degree of

Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £5 on the conferring of the degree of Ch.M.

The Matriculation Examination is held in July and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The Second and Final Examinations are held in March and July, the examination for Ch.M. in July only.

The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The appointments open to students are numerous and of considerable monetary value, and there are probably more here than are available at any other medical centre. The principal are:—Nine Entrance scholarships, the Leech fellowship of £100; Entrance scholarships in medicine, £100 (towards College and Infirmary fees); Manchester Grammar School scholarships, two or three of not less than £15 or more than £30 per annum for three years; Turner scholarship of £20 to students who have completed a course of medical study in the University; Platt physiological scholarships, two of the value of £50 each; Platt zoological and botanical scholarship, £50; Professor Tom Jones' memorial surgical scholarship of £100, awarded triennially; two Dauntsey medical entrance scholarships, value £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25 to £50, awarded annually; and many others.

Fees.—Composition fee, 83 guineas, in three instalments of 23, 30 and 30 guineas. Hospital practice: Composition fee, £42, or two instalments of £22 each.

Dental Fees.—Composition fee, £60, payable in two sums of £30 each. Hospital practice, £21.

BIRMINGHAM UNIVERSITY.

The University of Birmingham grants Degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these Degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(*a*) The previous examination of the University of Cambridge; (*b*) Responsions of the University of Oxford; (*c*) The matriculation examination of any other University in the United Kingdom; (*d*) The leaving certificate (higher) of the Oxford and Cambridge Boards; (*e*) The Oxford or Cambridge junior local examination (first or second class honours); (*f*) The Oxford or Cambridge senior local examination (honours); (*g*) The College of Preceptors examination for first-class certificate.

Matriculation Examinations are held in June and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher Degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital.

THE GENERAL AND QUEEN'S HOSPITALS.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 8,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Gilbert Barling, Dean, Medical Faculty.

UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The course of study for the Degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

The University provides a complete curriculum for these Degrees, and possesses modern and well-equipped laboratories and class-rooms for the teaching of all the subjects.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

Diplomas.—Diplomas have been instituted in Public Health (D.P.H.), Topical Medicine (D.T.M.), and Veterinary Hygiene (D.V.H.). Special diplomas are also granted in Anatomy, Bacteriology, Bio-chemistry, and Parasitology after a course of study of three terms in the subject chosen and allied subjects.

A Diploma (L.D.S.) and Degrees (B.D.S. and M.D.S.) have recently been instituted in dental surgery. These are only conferred upon students of the University. Particulars may be obtained from the Registrar.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees and qualifications of the other licensing bodies.

Hospitals.—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1,127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an unrivalled field for clinical education and study, and all are within easy access from the university. The period of hospital practice extends over the last three years of medical study. During the first two years no student will be permitted to change his attendance from one general hospital to another except at the commencement of an academic term. It is a regulation of the school that not more than five of the six terms of these two years shall be spent at any single General Hospital. During the final year of hospital practice a student is permitted to attend the practice of all the general hospitals without restriction. The regulations demand only that his attendance shall be regular and to the satisfaction of the Hospital's Board. There are a large number of appointments to House Physicianships and surgeonships both at the general and special hospitals, which are open to qualified students of the School. These appointments (20) in most cases carry salaries varying from £60 to £100 per annum.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £800 are awarded annually. A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the Pathological department. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatological Pathology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1907 the subject will be Clinical Medicine. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the Science Course for the University Degree in Medicine.

Communications should be addressed to the Dean, Professor Benjamin Moore, M.A., D.Sc., the University, Liverpool.

THE ENGLISH COLLEGES.

THE medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.

CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and physics, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates.

The subjects of the first professional examination are chemistry and physics, practical pharmacy, and elementary biology. A candidate is allowed to take this examination in three parts at different times. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follow:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are, —Part I. Medicine, including medical anatomy: pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynæcology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follow:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynæcology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Members.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 5s. is deducted. In either case £6 6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Conjoint Board.

FELLOWSHIP.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

FEES.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final. The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

SOCIETY OF APOTHECARIES OF LONDON.

PRIMARY EXAMINATION.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (*a*) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (*b*) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (*a*) or (*b*) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

ST. BARTHOLOMEW'S HOSPITAL.—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, chemistry, biology, physics, and chemical pathology, and two additional operation theatres have just been built. A new block of buildings is in course of erection at a cost of £120,000, and will contain new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining hall and a common-room for students, &c. Collegiate residence is permissible, subject to the ordinary rules.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and assistant surgeons, and to the physicians and surgeons in charge of special departments, are appointed every three months without fee.

Scholarships, &c.—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and a Jeaffreson exhibition, value £20; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize; Holden Research Scholarship in Surgery, value £105.

Fees.—By payment of an annual composition fee, a student is entitled to attend all the courses of instruction, and to hold the various clinical appointments. For students commencing their medical studies:—Entrance fee, 30 guineas; annual fee, 30 guineas, for five years, or a single payment of 165 guineas. A student on qualification at the end of the five years is not liable for any further fees, and receives a perpetual ticket. Should he fail to qualify in this time, the fee for further instruction is 10 guineas for each six months. Fees for University students:—Entrance fee, 20 guineas; 30 guineas, annually for two years, and 10 guineas for each six months if not qualified. Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas.

Dean, Dr. T. W. Shore, will furnish further details on application.

CHARING CROSS HOSPITAL.—The Winter Session will be opened on Monday, October 1st, by the delivery of the sixth Biennial Huxley Lecture by Professor Ivan Petrovitsch Pawlow, of St. Petersburg.

The school attached to this hospital is situated in Central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-room, and chemical theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen, and electrical departments, there are several scholarships and prizes, particulars of which can be obtained of the Dean.

Appointments.—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; obstetric registrar, six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks and dressers are appointed in all the general and special departments of the hospital.

Fees.—For the curriculum of study required by the various examining bodies and hospital practice, 115 guineas in one sum, by sessional payments as follows: Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every Winter Session, and one of 10 guineas at the beginning of every Summer Session so long as the student remains in the school. For dental students, 55 guineas in one sum, or 61 guineas payable in two instalments of 31 and 30 guineas respectively.

For prospectus and further information, application should be made to the Dean.

The composition fee for sons of registered medical practitioners is 105 guineas, and the fee, by instalments, 115 guineas. For dental students. 55 guineas in one sum, or 61 guineas payable in two instalments of 31 and 30 guineas respectively.

ST. GEORGE'S HOSPITAL.—This hospital is situated in the West End, facing Hyde Park. It contains 351 beds, and special wards for ophthalmic cases and diseases of women.

Appointments.—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of £100; two medical registrars, with salaries of £200 per annum; a surgical registrar with a salary of £200 per annum; an administrator of anæsthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; two or more demonstrators of anatomy with a salary of £50 each; and assistant demonstrators. All offices are open to candidates without additional fee.

By arrangement with the University of London, all students for the first, second, and third years of the curriculum carry out the necessary courses of instruction at either King's College or University College. The entire teaching of the school is devoted to clinical subjects.

There are two scholarships open to University students, particulars of which will be furnished by the Dean.

Fees.—For first year, £21 or £26 5s., according to the course. For second and third years, £57 15s. in one sum or £63 in two instalments. Students entering their names on the books before commencing the preliminary or intermediate subjects pay no entrance fee. Entrance fee, 10 guineas; annual composition fee, 30 guineas.

GUY'S HOSPITAL.—This hospital is situated on the Surrey side of London Bridge, and contains 602 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital has been constructed. An obstetric registrar and tutor and an ophthalmic registrar and tutor are appointed to augment the teaching in the special departments, in addition to those attached to the general surgical and medical wards. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study within the walls of one hospital will be appreciated by those intending to practise dentistry. A new museum for pathological specimens and additional lecture and class rooms were opened this year.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house physicians, sixteen out-patient officers, sixteen assistant house surgeons, eight obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in

pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150.

Fees.—A new system for payment of composition fees has been recently instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

King's College Hospital.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light is installed throughout.

Scholarships.—Two scholarships of the value of £100 each; a scholarship, value £50, is open to students of a British University who come up to London to complete their curriculum; and one of £40 for fifth year students. In addition, students may compete for the Carter, Todd, Tanner prizes, and all class and clinical prizes.

Appointments.—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, *viz.*, senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

Special courses of lectures and practical instruction in the chemical, physical, physiological, and other laboratories have been arranged for students preparing for preliminary scientific, intermediate, M.B., and other examinations of the University of London.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

London Hospital.—This hospital is the largest in Great Britain, containing, as it does, 929 beds. It has, moreover wards and a teaching staff for almost every special department in the domain of medicine; the scholarships and prizes are many and valuable.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, materia medica museum, &c., and the new bacteriological department with general laboratory, research laboratories and class rooms for D.P.H. work are now open.

Appointments.—The "House" appointments, which are numerous, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in some instances with salary also.

Fees.—Perpetual fee for lectures, demonstrations and hospital practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the first, second, and third years respectively, 130 guineas; or, if in one payment, 120 guineas. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school, elsewhere) 60 guineas. This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London. Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

Note.—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures or for hospital practice. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Fuller particulars can be obtained of the Warden, Mr. Munro Scott.

St. Mary's Hospital.—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is now completed, and will be opened as soon as funds will permit; this will raise the number of beds to 350, clinical laboratory, and a clinical theatre. A new X-ray Department has recently been established in the Out-patient Department of the hospital. The Athletic Ground (eight acres) is situated at North Kensington, and is easy of access from the hospital. During the past year a Department for Therapeutic Inoculation has been instituted under Sir Almroth Wright, F.R.S., the work being carried on in two special laboratories in the Museum Buildings.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anæsthetists are appointed in each year, and receive board and residence in the Hospital.

Scholarships, &c.—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship in natural science, of the value of £78 15s., and two of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from any British University. The scholarships will be awarded by examination on September 25th, 26th, and 27th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Preliminary Scientific Course.—A complete course of instruction in chemistry, physics, and biology, recognised by the University of London as an approved course for internal students, is held throughout the year. Students may join in October, January, or April.

Middlesex Hospital.—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, children's diseases, and electrical treatment (X-ray and Finsen light). Wards are also devoted to cases of uterine disease. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

Appointments.—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

Scholarships, &c.—Two entrance scholarships of the value of £100 and £75 in Arts and Science respectively. One entrance scholarship of the value of £50, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) "Emden" Cancer Research Scholarship, £100. "Richard Hollins," Research Scholarship, £105. Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal and scholarship, value £55, in surgery and

surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynæcology; an exhibition of 10 guineas for anatomy and physiology to second years' students as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students is 145 guineas. For those who have passed the preliminary science examination 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

ST. THOMAS'S HOSPITAL.—This hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament and contains 602 beds, in constant use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging; two resident casualty officers at a salary of £100 per annum. Two hospital registrars, at an annual salary of £100 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house physicians, four house physicians to out-patients, four house surgeons, four house surgeons to oui-patients, two obstetric house physicians, two ophthalmic house surgeons are appointed each six months, and eight clinical assistants in the special departments each three months.

Scholarships, Prizes, &c.—Three entrance scholarships are offered for competition in September, *viz.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

UNIVERSITY COLLEGE AND HOSPITAL.—The hospital with college opposite are situated in Gower Street, not far from Euston railway terminus. The number of beds available for teaching purposes is *277*.

The new buildings for University College Hospital, completed by the generosity of the late Sir Blundell Maple, Bart., are now completed, and will be opened by H.R.H. the Duke of Connaught, on Tuesday, November 6th, 1906.

The new buildings for the Medical School, now in course of erection through the generosity of Sir Donald Currie, will be ready shortly, and will contain accommodation for undergraduate and post-graduate students in all departments of medical study subsequent to the intermediate course.

Appointments.—Eight house physicians, eight house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance scholarship of the value of 135 guineas, and two exhibitions of 55 guineas each, and the Epsom free medical scholarship for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Dr. Fellowes' clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c,, gold and silver medals or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry, two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

Composition Fees.—The following have been grouped to meet the requirements of the various examining boards: A.—For the Courses required by the University of London. 1. For the Preliminary Scientific course: 25 guineas, entitling to one attendance. 2. For the Intermediate Course: 60 guineas, if paid in one sum; 62 guineas if paid in two instalments. 3. For the Final M.B., B.S. Course: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham.

B.—For the Medical education required by the Examining Board in England and the Society of Apothecaries: 4. For the Course required for the First Examination: 30 guineas entitling to one attendance. 5. For the Second: 50 guineas, if paid in one sum; 51 guinesa, if paid in two instalments. 6. For the Course required for the Third Examination: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments.

The composition fee in each case entitles to attendance on Lectures and Hospital Practice during three years.

C.—For Dental Students. Composition fee for the Courses required for the L.D.S., 65 guineas; or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas.

Students may repeat attendance at the Courses in chemistry and physics for £3 3s. (inclusive) and in elementary biology for £2 2s.

It should be noted that under the arrangement with the University of London, that body controls the medical science section of the medical school now, while the advanced medical subjects, that is the subjects after the intermdiate course, are controlled by the University College Hospital Medical School.

WESTMINSTER HOSPITAL.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The

Class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(*a*) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and either Greek, French, or German. University scholarships, £40 and £30; subjects, anatomy and physiology. Natural science scholarship, £60, subjects, same as for Prel. Sci. of University of London. Natural science scholarship, £40, subjects, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (*b*) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40, University scholarships, £40 and £30, subjects same as in winter session. (*c*) Prizes, to be competed for by unqualified men. Chadwick, 20 guineas for students of any year not exceeding fifth. Bird medal and prize, £14 for students who have completed fourth winter session. Sturges prize in clinical medicine, £10, clinical surgery prize, £5. And class prizes in the various subjects.

Fees.—(*a*) For course required by Conjoint Board. In one payment of 120 guineas, or two payments of 65 guineas each, payable on entrance and at the commencement of second year respectively, or by six payments, distributed over six sessions, of 24 guineas each. (*b*) For the entire course of the University of London the composition fee is 140 guineas. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments, of £27 10s each.

LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).—The school is situated in Hunter Street, Brunswick Square, W.C., and the Royal Free Hospital is in Gray's Inn Road, close to the School. The school was re-built in 1898, and the laboratories are fully equipped for all the work required for the preliminary Scientific and Intermediate M.B. examinations of the University of London. A course of study is specially arranged for the work required by the Conjoint Colleges of Scotland and the Society of Apothecaries. Students are also prepared for the examinations of the University of Durham and other Universities. The Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in medicine, surgery, obstetrics, ophthalmology and dermatology. Students hold clerkships and dresserships in each department.

Appointments.—One house physician, one house surgeon and a senior and junior resident obstetric assistant are appointed yearly. There are also many non-resident appointments including the anæsthetist and assistant anæsthetists, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

Scholarships.—A School Scholarship of £30, and a St. Dunstan's Medical Exhibition of £60 yearly for three years, extendible to five years, are offered annually. In addition to these there are various scholarships and prizes offered from time to time, including the Bostock Scholarship of £60 a year for two years, extendible to four years; the Stuart Mill Scholarship of £30 a year for four years; the John Byron Bursary of £20 a year; and the Mabel Webb Research Scholarship of £30 a year.

Fees.—The fee for the Intermediate and Final M.B. University of London course is £135 in one sum, or £145 in the following instalments:—first year, £45; second year, £40; third year, £40; fourth year, £20. The fee for the Preliminary Science classes is £25. The fee for the course for the Conjoint Colleges or Society of Apothecaries, including Elementary Science, is £140 in one sum, or in the following instalments:—first year, £50; second year, £40; third year, £30; fourth year, £20. Further particulars can be obtained from the Secretary, Miss Douie, M.B., 8, Hunter Street, W.C.

EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The Royal Institute of Public Health, 37, Russell Square, was founded in the year 1886, with the object of obtaining the registration of public health diplomas and the further statutory requirement that all Medical Officers of Health should possess such a qualification, by which means it has succeeded in placing at the head of every public health administration in the Kingdom, a properly trained and specially qualified medical officer. The Council, with the object of providing a Central Institution in London, not only for instruction for the diploma and for scientific work in connection with public health, but also one to which those engaged or interested in preventive or tropical medicine may resort for purposes of reference or social intercourse have acquired large and important premises for the purposes of the Institute, providing a common room for the use of Fellows and Members, a lecture room, a reference library, laboratories for bacteriological and chemical and physical research, and laboratories in which the course of instruction for the diploma in public health can be taken. These laboratories have been fitted up with all modern improvements, and are intended to supply a want long felt in London, and to place the Metropolis, in this respect, on an equality with many provincial and University cities.

The Institute is recognised as a public educational institution by the University of London, and its courses of instruction by the Universities and the Royal Colleges of Physicians and Surgeons.

In pursuance of the above objects, the Institute publishes monthly *The Journal of Preventive Medicine.*

Facilities are also afforded for municipal authorities, private medical practitioners, and others to obtain bacteriological and chemical reports.

The Institute is under the patronage of His Majesty the King, and the Right Hon. Lord Strathcona and Mount Royal is President. The teaching staff consists of the Principal, Professor William R. Smith, M.D., D.Sc., F.R.S.E., Barrister-at-law; Demonstrator of Bacteriology, Carl Prausnitz, M.D., Breslau; Demonstrator of Chemistry, Mr. C. E. Harris, Ph.D.; Director of Parisitological Dept., Dr. Louis Sambon.

The next annual Congress (1907) will take place at Douglas, Isle of Man, under the Presidency of the Right Hon. Lord Raglan, Lieutenant-Governor of the Island.

THE ROYAL DENTAL HOSPITAL.—The teaching and hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital was opened in March, 1901, and is complete in every detail with modern appliances, and the school is the most thoroughly equipped of any in the United Kingdom. The clinic of the hospital is unrivalled, no less than 98,588 cases being treated in 1905. The following scholarships and prizes are open to all full term students:—Entrance scholarship, of the value of £20, awarded in October. Subjects: Chemistry and dental mechanics. Saunders scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks in the various class examinations. Storer-Bennet research scholarship of the value of £50, awarded once in three years. Robert Woodhouse prize, of the value of £10, for

practical dental surgery. Class prizes are awarded by the various lecturers.

Provision is made for teaching mechanical dentistry as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators.

The school contains an excellent library and a well-arranged museum.

Fees.—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum, namely, two years' instruction in mechanical dentistry and two years' hospital practice and lectures, is £150 if paid in one instalment, or 150 guineas if paid in three instalments of 50 guineas. For one year's instruction in mechanical dentistry the fee is 50 guineas. For one year's hospital practice, £21. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

NATIONAL DENTAL HOSPITAL.—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 2nd. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for two years' hospital practice required by the curriculum, including lectures, is £40. (See advt.)

LONDON SCHOOL OF TROPICAL MEDICINE (University of London).—This Institution is the outcome of a suggestion by the Right Hon. Joseph Chamberlain, H.M. late Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seamen's Hospital, than which no more suitable spot could be found, as ships arrive there in great numbers from the Tropics, affording immediate opportunity for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Information as to fees, &c., can be obtained of the Dean or the Secretary.

Medical students are admitted to the practice of the following Metropolitan hospitals to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

WEST LONDON HOSPITAL, Hammersmith. — This contains 175 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been greatly enlarged, contains 167 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEM ROYAL HOSPITAL.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen's Square, W.C., contains 200 beds. It has on its staff men of European reputation, and the institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

LONDON TEMPERANCE HOSPITAL.—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

METROPOLITAN HOSPITAL, Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

TOTTENHAM HOSPITAL, N.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

HOSPITALS FOR CONSUMPTION.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 321 beds in the two buildings. There are four house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

MOUNT VERNON HOSPITAL, Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 145 beds, and at Northwood with 100 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—(80 beds.)—This hospital has been enlarged by the addition of a very complete out-patients'

department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

THROAT AND EAR HOSPITALS.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—This hospital has been recently rebuilt and contains 40 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual out-patient attendance of nearly 50,000. Major and minor operations daily (Mondays excepted) in different theatres. Four senior and forty-two junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; perpetual attendance, £10 10s. Further details can be had by applying to the Dean.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn Road.—In addition to the in-patient department, which is now undergoing enlargement by the addition of more beds and an operating theatre, there is an extensive out-patient department in which clinical demonstrations are given daily at 2.30 p.m. Full facilities are afforded for acquiring sound practical experience of the subjects. Twelve clinical assistants—who must be duly qualified—are elected to assist the surgeons. Operation days—Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months', £5 5s. Full details of this institution and post-graduate work can be obtained on application to the Dean.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital was founded in 1838, and is situated in Grafton Street, Tottenham Court Road. The out-patient department is open daily at 2.30 p.m. to practitioners and students for acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, and Thursdays at 9 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas. During the forthcoming session demonstrations will be given by members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Short practical classes will also be held in clinical pathology and surgical anatomy. Weekly clinical lectures are given by the staff on the special disease treated at the hospital.

WOMEN AND CHILDREN.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynæcology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynæcology. The success of the staff in this department has gained for them a European reputation. There are 47 beds.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—This important institution, situate in South London, has been in a transition state for some time past, having been partly rebuilt and appointed on ambitious lines, and when completed, which it is expected to be shortly, will contain 200 beds.

HOSPITAL FOR SICK CHILDREN in Great Ormond Street, Bloomsbury, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, £2 2s.; perpetual, £3 3s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital is open to pupils of the different hospitals and medical schools of London and medical practitioners on conditions to be ascertained from the Secretary.

EYE HOSPITALS.

ROYAL LONDON OPHTHALMIC HOSPITAL, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

SKIN HOSPITALS.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 50 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence on Thursday, October 4th, at 6 p.m., in the Lecture Room of the Hospital, Leicester Square. The subject of the opening lecture will be "Baldness." The Out-patient Department has just been rebuilt at a cost of £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation on Monday, Thursday and Friday afternoons. Clinical demonstrations are given every Friday (Dr. Morgan Dockrell), at 2 p.m.; Wednesday (Dr. Saville, at 3 p.m.; and Tuesday (Dr. Eddowes), at 2 p.m. on Selected Cases (See Advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Great Portland Street), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the London Skin Hospital, in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the Metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration, are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, laryngology, urinary analysis, gynæcology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery and practical anatomy with dissecting.

A complimentary ticket for three days, admitting to *cliniques* and lectures, is issued to any medical practitioner on personal application at the college. The annual subscription for medical practitioners of either sex, holding qualifications granted in any of H.M.'s dominions—wherever resident—is One Guinea. Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S., 22, Chenies Street, W.C.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith Road, W., contains 159 beds; the post-graduate course was started in 1895, and this is the original post-graduate college in London attached to a general hospital. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. There are lectures every evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, diseases of the eye, throat, X rays, anæsthetics, intestinal surgery, etc.

Fees.—The fee for the hospital practice including all the ordinary lectures and demonstrations, is £1 1s. for one week; £2 2s. for one month; £5 5s. for three months; £8 8s. for six months; £12 12s. for one year, and £25 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery is £2 2s. A prospectus containing full particulars will be forwarded on application to Mr. L. A. Bidwell, Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—This post-graduate school is established in connection with the Tottenham Hospital, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations of various branches of medicine, surgery and gynæcology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anæsthetics, radiography and dentistry. Cliniques, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which will be limited, are arranged in gynæcology, the surgical diseases of children, including orthopædic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology, and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of 5 guineas. Additional information with a syllabus of lectures demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, 142, Harley Street, W.

PROVINCIAL MEDICAL SCHOOLS.

BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.—The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary science examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London. Well-equipped laboratories are now provided for anatomy, physiology, bacteriology, and pathology. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments, and special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

Appointments.—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum. There are one medical entrance scholarship, value £75, awarded annually, two Martyn memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbits memorial prize, value £9, for proficiency in practical surgery, Henry Marshal prize, £12; Clarke Scholarship, £15; Sanders Scholarship, £22 10s.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures and hospital practice, and including all fees, except vaccination and small charge for board of midwifery student, 133 guineas. If in two instalments, 80 guineas at first session and 60 guineas in the beginning of the second year. Dental composition fee, 75 guineas, including all lectures, practical classes, and hospital practice. Clinical fees (if the composition fee has not been paid)—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual, medicine and surgery, 40 guineas.

Prospectus and further information on application to the Dean, Professor Edward Fawcett, M.D.

SHEFFIELD UNIVERSITY COLLEGE.—*Faculty of Medicine.*—The Winter Session, 1906-7, will commence in the new University building on Wednesday, Oct. 3rd.

The University was opened on July 12th, 1905. by the King. The plan of the buildings is that of four blocks, enclosing a quadrangle, 154 ft. by 110 ft. The medical department occupies the entire north wing overlooking the quadrangle on one side and Weston Park on the other. The anatomical department occupies about two-thirds of the upper ground floor. The dissecting room has been designed and equipped to meet all modern requirements of the student of anatomy. The lecture theatre is provided with a lantern of modern type illuminated by the electric arc. The anatomical museum has a gallery which is set apart chiefly for anthropological and morphological collections. The floor space affords accommodation for bones, models, and spirit specimens mounted in glass jars. Research laboratories and private rooms are provided for the professors and demonstrators. The department of physiology occupies the first floor. In the general laboratory, a large and well lit room, accommodation is provided for microscopical work at a bench running the full length of the laboratory beneath the windows; the space behind is occupied by movable tables, each equipped for the purposes of experimental work, an arrangement which enables the students to work either singly or in small groups. The fixed equipment of the room

is designed to provide power for machinery, gas, electricity, and water wherever the tables may be situated. The second laboratory for chemical physiology is fitted with benches, fume cupboards, &c. In addition a considerable portion of the space in this room is devoted to and equipped for work of a more advanced type. Opening into this laboratory are a balance room and two rooms fitted for photography, spectroscopy, &c. Opportunities are afforded for research work in three special rooms. One, beautifully lighted by windows in two of its walls, is equipped for general research, another a room which can be darkened for optical work and photographic recording; and a third in the basement is provided with the solid pillars, &c., necessary for work with delicate instruments requiring great stability. In the lecture theatre, a large amount of space has been left for the demonstration of experiments, and is equipped with the larger pieces of apparatus necessary for such work. The whole upper storey of the medical block is occupied by the Department of Pathology. The students' laboratory, a very large and lofty room, is fitted and equipped with every modern appliance for microscopical and bacteriological work. The incubating room, built into the centre of the pathological department is so arranged that it may be kept at a constant temperature, thus replacing the ordinary incubating ovens. The museum is spacious and is furnished with a gallery. Research laboratories are provided. On the upper ground floor are well-furnished lecture rooms for other subjects, and the materia medica museum. The library of the Sheffield Medico-Chirurgical Society, to which students are admitted, is situated on the ground floor overlooking the quadrangle.

Hospital practice is taken out at the Royal Infirmary (255 beds) and at the Royal Hospital (165 beds), both of which institutions have special departments for diseases of the eye, ear, and throat, and skin. At the latter there is also an extensive dental department.

Composition fee, £45; or in two payments, viz., £26 on entrance, £22 within twelve months afterwards.

Composition fee for medical and surgical hospital practice, £36 5s.; or in two payments, viz., £18 18s. on entrance and £18 18s. within twelve months afterwards.

Composition fee for lectures and practical courses, £80 in one payment or in three instalments of £24, £28, £28.

An Entrance Scholarship of the approximate value of £100 is awarded on the results of the Matriculation Examination of the Joint Matriculation Board held in July.

Students of either sex are admitted to the degrees of the University.

The Kaye scholarship, for second year students, natives of Sheffield, is awarded annually, under certain regulations. Gold Medal for clinical medicine and clinical surgery; medals and certificates awarded annually.

UNIVERSITY OF WALES, CARDIFF SCHOOL OF MEDICINE.—This college, which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific Examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in Materia Medica and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England

Courses of lectures to midwives, adapted to the requirements of the Central Midwives' Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

UNIVERSITY OF LEEDS.—This school of medicine, attached to this recently incorporated University, was originally founded more than seventy years ago as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened twelve years since, contains one of the finest dissecting rooms in the Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 524 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken. Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, a hospital for women and children, and a maternity home, all of which are open to students of the school.

Scholarships, Prizes, &c.—(1) An entrance scholarship of £71 0s. 6d. There is also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10. Thorp prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize of £5 in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is £71 0s. 6d. for University

students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

At the General Infirmary, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary.

Degrees and Diploma in Dental Surgery are obtainable at this university, being Bachelor of Dental Surgery (B.Ch.D.), and Master of Dental Surgery (M.Ch.D.). Candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not attained the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction, approved by the University, extending over not less than four years and that they have completed a pupilage of three years, two of such years at least, having been taken before the First Professional examination. Candidates are required to satisfy the Examiners in the several subjects of the following examinations: A preliminary examination in Arts; a Preliminary examination in Science; the First Professional examination; and the Final examination.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school, which has for its object research into Tropical Diseases and Improvement in Tropical Sanitation, was founded in Liverpool in 1899 by Sir Alfred Jones, K.C.M.G., who is the chairman of the school. The research work of the school is carried on at the Johnston Laboratories, in Liverpool University. The clinical work is carried on at the Royal Southern Hospital. A special feature of the work of the Liverpool School of Tropical Medicine has been the despatch of a large number of important medical expeditions to various places in the tropics, especially West Africa. Although the School has only been in existence for a short time it has already sent over a dozen of these expeditions. In addition, the School has issued a number of valuable publications and monographs on subjects connected with tropical diseases. The Duke of Northumberland, K.G., is Hon. Vice-President; Sir Alfred L. Jones, K.C.M.G., Chairman of Council; and Mr. Wm. Adamson, Vice-Chairman; and the following is the school staff. Sir Alfred Jones, Professor Ronald Ross, C.B., F.R.S., F.R.C.S.; Walter Myers Lecturer, J. W. W. Stephens, M.B.Cantab; Lecturer in Economic Entomology and Parasitology, R. Newstead, A.L.S., F.E.S. Lecturer in Tropical Diseases of Animals, H. E. Annett, M.D.; Director of Tropical Research at Runcorn, J. L. Todd, B.A., M.D., C.M. McGill; Assistant Lecturers, H. Wolferstan Thomas M.D., C.M. McGill, Anton Breinl, M.U., Dr. (Prag.) Demonstrators and Research Assistants, Allan Kinghorn, M.B., E. N. Tobey, A.B., A.M., M.D. Dean: Professor Rubert Boyce, M.B., F.R.S. Hon. Secretary A. H. Milne, B 10, Exchange Buildings, Liverpool.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached :—

BATH ROYAL UNITED HOSPITAL.—This is a well-appointed hospital in the West of England, with 130 beds, at which students can obtain clinical instruction The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months', ten guineas.

BRADFORD INFIRMARY.—The hospital contains 220 beds. Non-resident pupils are received and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

BRIGHTON SUSSEX COUNTY HOSPITAL contains 190 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

LIVERPOOL NORTHERN HOSPITAL, which has recently been rebuilt, now contains 246 beds, and is completely equipped with the most modern appliances. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £6 6s.; three months, £4 4s.; practical pharmacy, £2 2s.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NORTHAMPTON GENERAL INFIRMARY.—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains 160 beds, a splendid library, in which the Reading Pathological Society holds its mettings.

THE ROYAL HOSPITAL, Portsmouth.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognised by the Examining Boards. The number of beds is 120. The fees are the same as at all similar institutions,

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 200 beds (including special children's wards), and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards. Arrangements can be made by which students can attend midwifery on application to the House Surgeon.

NORTHAMPTON GENERAL HOSPITAL.—This hospital contains 174 beds; it has been recently enlarged and re-arranged. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. *Fees;* Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

A PRESENTATION to the anti-vivisectionist leader, Dr. Walter Hadwen, has just taken place. In recognition of Dr. Hadwen's valuable services to the anti-vivisectionist cause, a beautiful silver rose-bowl and a sum of money were handed to him by the subscribers.

BY electing Miss Frances Ivens, M.B., M.S., London, the Stanley Hospital has the distinction of receiving on its honorary medical staff the first lady doctor to be appointed to a general hospital in Liverpool.

Ireland.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student :—

COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. ...	£122 6s. 6d.
Royal College of Surgeons School	£124 19s.
Catholic University School ..	£124 19s.
Queen's College	About £110

COST OF DIPLOMAS OR DEGREES.

Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University	£15.
Conjoint Royal Colleges ..	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £232 10s. 6d. according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding" although not officially recognised, occupies a position almost identical with that of the extra-mural instruction in other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion.

All the Dublin schools require fees to be paid in advance.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is *supposed* to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be remembered that no credit is given for studies or attendance until the entry is regularly made, The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, *e.g.*, the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Examination passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows :—1. English language, including a specified author, dictation, grammar, and composition ; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions ; (*b*) algebra. including simple equations ; (*c*) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects :—(*a*) Greek, (*b*) French, (*c*) German.

THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes :—*a*. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b*. Those who take the licence of the conjoint Royal Colleges of Physicians and Surgeons. *c*. Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. *d*. Those who take the licence of the Apothecaries' Hall. *e*. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows ;—

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the degree of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows :—Lectures, £66 13s. 6d. ; Hospitals, £55 13s. ; Degree Fees, £27.—Total, £149 6s. 6d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £232 10s. 6d.

Important new regulations come into force in the Summer Session of 1906. One of the main results of these will be to diminish the extent of the Arts course for medical students, while at the same time preserving

the advantage of an Arts education by rendering the attendance on certain lectures compulsory. Changes in the medical examinations will also take place, but the curriculum itself is practically unaltered.

In addition to its ordinary qualifications the University grants the following higher degrees :—

Doctor of Medicine.—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects :—Practice of midwifery, gynæcology, anatomy of female pelvis and elementary embryology, and clinical gynæcology. Fee for this degree, £5.

Diplomate in Medicine, Surgery, and Midwifery — Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The course and examination is the same as for the degrees, except that the lectures and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not have obtained an Arts degree. Fees for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the lectures on botany and zoology, passing the preliminary scientific examination in those subjects, and paying the degree fees.

Diploma in Public Health.—The candidate must be an M.D. or a Graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge, must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months under an approved Officer of Health.

Degree and Licence in Dental Science.—Candidates for the degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for five years. Two examinations must be passed—namely, the Previous Dental at the end of the second year, and the Final Dental at the end of the fifth year. Candidates for the Licence are required to matriculate in Arts, but need not proceed further in the Arts course. The course of study is the same as for the degree with the exception that no lectures in pathology or bacteriology are required. The total fees for the licence, including the premium for Dental Mechanics (£100), are £200 17s., while those for the degree are about £210, to which must be added the cost of the B.A. degree.

Post-Graduate Classes.—A short post-graduate course is now given annually in July in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynæcology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

Royal Services School.—The object of this school is to prepare candidates for the Indian Medical Service, and Royal Army Medical Service. It is conducted on a comprehensive scale, and affords special opportunities for operating on the cadaver, and for the study of commentaries. Two sessions are held yearly, each lasting for about ten weeks.

THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, *i.e.*, the matriculation examination of this University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees :—

M.B., B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., and M.A.O. It also confers a Diploma in Public health and a Diploma in Mental Diseases.

All degrees are open to persons of either sex.

The University examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about October 1st.

All candidates for any degree must pass the matriculation examination and the first University examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first University examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1 ; for the degree examination, £2 ; for the diploma, £10.

In addition, the following degrees are granted :—

Diploma in Public Health.—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. Subjects.—Meteorology, bacteriology, chemistry, physics, vital statistics, hygiene, sanitary engineering, architecture and law.

The M.D. Degree.—Conferred only on graduates in medicine of the University of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and be required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom Fee, £5.

The M.Ch. Degree.—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. The examination comprises surgery, both theoretical and operative surgical anatomy ; ophthalmology and otology Fee, £5.

The M. A. O. Degree.—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. The examination comprises midwifery and diseases of women and children. Fee, £5.

Prizes, &c.—First Examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class exhibitions of £25, and two second-class of £15, and the Dr. Henry Hutchinson Stewart Medical Scholarships, value £10 a year for three years. The latter are awarded in psychological medicine, diseases of the nervous system and anatomy, physiology and pathology of brain, cord, and nerves. Competition among medical graduates of not more than three years' standing. Fee £2. Value £50 a year for three years.

Third Examination in Medicine.—Two first-class exhibitions of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first-class exhibitions of £40 each, and two second of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

These examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In common with the English Colleges, the subjects of the First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional examination.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 276.

ROYAL COLLEGE OF PHYSICIANS.

This College issues a Licence in Medicine and a Licence in Midwifery to Registered Medical Practitioners.

Licence in Medicine.—The subjects of examination are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

Licence in Midwifery.—The subjects of examination are:—Gynæcology and Midwifery. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to Practise Medicine £15 15s. Fee for the Licence to Practise Midwifery £5 5s.

Membership.—The Membership is open to University Graduates in Medicine and to Licentiates of the Royal Colleges of Physicians of the United Kingdom. The Examinations for Membership are held in January April, July, and October, and such other times as the President may appoint.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothecaries' Society of London, and the Apothecaries' Hall, Dublin, granted since October, 1886, are admitted to examination without further evidence of study, but candidates who hold medical qualifications only, including the L.S.A. and L.A.H., granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s. The fee for a special examination is £31 10s.

A diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (*a*) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (*b*) attendance or six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (*c*) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

Fellowship.—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. Examinations are held the third Mondays in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination (except during the months of August and September) if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Students, not either Licentiates or Graduates in Surgery, are permitted to present themselves for the *Primary* Examination under Grade I.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery, surgical anatomy, and surgical pathology.

Fees.—Grade 1.—For Licentiates of College; Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum, and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and he also possesses the privileges of an apothecary.

There are four professional examinations, the total fees for which amount to 21 guineas. Women are eligible for the diploma.

Registered Medical Practitioners will receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of ten guineas; if medicine or surgery is required, five guineas extra will be charged.

The fees payable for each examination are as follows: First Professional, £5 5s.; Second, £5 5s.; Third, £5 5s.; Final Examination, £6 6s.

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the Final. If he has passed only in some of the subjects in a given examination, he has to pay the whole of the fee for that examination.

The fees for re-examination are: For each subject, £1 1s., excepting in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, physiology, pathology, and ophthalmology, the fees for which are £2 2s. each.

The fee for the Third and Final, or Final alone, is £15 15s., when the other examinations have been taken elsewhere.

All examination fees are to be lodged in the Sackville Street Branch of the Royal Bank of Ireland to the credit of the Examination Committee.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall of Ireland, must, before proceeding to the Final Examination, produce evidence of having been registered as medical students for fifty-seven months; also of having attended courses of instruction as follows

One course each (winter course of six months) of the following: Anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology and surgery. Dissections, two courses of six months each.

Courses of three months.—Materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and a course in vaccination.

Medico-Chirurgical Hospital, twenty-seven months to be distributed over the last four years of study. The candidate may substitute for nine months in this, hospital attendance six months as a resident pupil.

Three months' study of fever.

Six months' practical midwifery and diseases of women.

Three months' practical pharmacy in a recognised clinical hospital or a recognized school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except in the subjects of physics and biology. This registration is not undertaken by the Hall.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar, at 40 Mary Street, Dublin.

LICENCE IN DENTAL SURGERY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The University of Dublin grants both a Degree and a Licence in dental surgery. To obtain the former, candidates must have taken a degree in arts; the licence is obtainable by all duly qualified persons who have passed the Public Entrance Examination of Trinity College, Dublin. The Royal College of Surgeons in Ireland grants a Licence in Dentistry.

Course of Study for the Licence in Dentistry.—Candidates are required to pass three examinations, *viz.*:—Preliminary (in General Education), Primary Dental, and Final Dental.

All information concerning this licence may be obtained from the Registrar of the College. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The subjects of examinations include physics, chemistry (including metallurgy), anatomy, physiology and histology, and surgery. The fees for the primary Dental Examination amount to £10 10s; and for re-examination, if rejected, £5 5s. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are examined in dental surgery, theoretical (including dental pathology), clinical, and operative; and in dental mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

The fees for the Final Dental Examination in the case of candidates holding the L.R.C.S.I., or students who have passed the Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. The fees for Final Examination of all other candidates, £26 5s., and for re-examination, £10 10s. The extra fee for Special Examination, £5 5s. A rejected candidate will not be again admitted to examination until after a period of three months.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candidate for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must have been on the "Medical Register" for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Royal University of Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions:—

The diploma is conferred only on graduates in medicine of the University. Candidates must give notice, in writing, to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination. Candidates who satisfy the examiners will be required to pay a further fee of £3 before the diploma is conferred. The subjects for this examination are those required by the Hutchinson Stewart Scholarship for proficiency in the treatment of mental diseases.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Every student of the school must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof.

Purser's past pupils, is awarded annually to the student who, at the ordinary June Intermediate Medical Examination, Part I., in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

Fitz-Patrick Scholarship.—This scholarship consists of the interest on £1,000. It will be awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOLS OF SURGERY.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. A refreshment room is now open, where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes, and lighted throughout by the electric light.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £31 10s.; the Carmichael Scholarship, £15; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

Two short post graduate courses are held in the year. Full particulars can be obtained from the Registrar.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £12 10s.; one final Conjoint Colleges Exhibition of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital. The Union Hospital, the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, and the District Lunatic Asylum are also open to students.

Prizes.—(1) Ten medical scholarships each year, value £20 each; (2) two Dunville studentships (one each year), value £150 each; (3) one Andrews student ship each alternate year, value £140; (4) numerous sessional prizes.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathological laboratories. From time to time lectures and demonstrations are given in the anatomical department on the Advanced Anatomy of the Nervous System, or some other department of applied anatomy.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmaries. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 27th, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Scholarships and Prizes.—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of about £32, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each

of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

QUEEN'S COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital is also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

Prizes.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine, from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close, of each session.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The Pharmaceutical Society of Ireland issue two qualifications and a certificate. The qualification of Registered Druggist; the qualification of Pharmaceutical Chemist; and the certificate of competency as Assistant to a Pharmaceutical Chemist.

Registered Druggist.—This qualification entitles the holder to keep open shop for the selling, retailing, and mixing of poisons. In order to obtain it, a person must now have served an apprenticeship or assistantship of four years to an apothecary, pharmaceutical chemist, or to a person who was, or would have been entitled to become, a registered chemist and druggist or a registered druggist, and be 21 years of age. He shall be examined with respect to his knowledge of English orthography and composition, arithmetic, and the weights and measures of the British Pharmacopœia, the appearance and properties of the various drugs and chemicals in general use, and as to the provisions of the Poisons Act. The fee is four guineas.

Examinations in Dublin (also in Belfast and Cork or other place if 12 candidates offer) on the second Tuesday of January, April, July, and October.

Pharmaceutical Chemist.—The qualification of a pharmaceutical chemist in Ireland confers greater privileges than is the case in England.

The subjects of examination are divided between the "Preliminary" and the "Licence."

The Preliminary examination is held on the first Thursday and following day of January, April, July, and October.

The fee is £2 2s. for the first attempt, and 10s. 6d. for each subsequent examination. Further particulars with reference to the subjects for examination may be obtained from the Registrar. The British Society's examination is accepted in lieu of this, as well as those recognised by the General Medical Council as a preliminary to medical studies.

Pharmaceutical Licence Examination.—This examination confers the title of Pharmaceutical Chemist and the right to compound medical prescriptions. Candidates must be 21 years of age, and must have passed the Preliminary prior to the service at practical pharmacy, unless such service was commenced before 1st January, 1907. They must, unless having passed the Preliminary previous to 1884, produce certificates of having served four years as assistant or apprentice to an apothecary or pharmaceutical chemist or four years to a druggist, two years to an apothecary or pharmaceutical chemist, also a certificate of having attended a course of practical chemistry of not less than three months' duration and of having actually worked at the bench for 100 hours during the said course at a recognised school; and also a course of botany and materia medica. The fee for examination is five guineas, and for re-examination two guineas. Examinations are held in Dublin on the second Wednesday and following day of January, April, July, and October.

Assistant to a Pharmaceutical Chemist.—The examination for the certificate of competency as an assistant may be described, in brief, as the same as that for the Licence, minus the examination in chemistry and botany, with the fee reduced to one guinea (half a guinea on the second and subsequent attempts). The Preliminary examination must be passed as for the Licence, and the usual 14 days' notice must be given. Candidates must have been engaged in practical pharmacy for four years.

Examinations are held on the Monday following the pharmaceutical Licence examination or on such days as the Council may direct.

DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

SESSION 1906—1907.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of agriculture, chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (*a*) in agriculture, and (*b*) in science and technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Session commences on Tuesday, October 2nd.

The courses of chemistry, physics, botany, geology, and mineralogy and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

The Entrance and Science Scholarship Examinations are held about the first week in July, and the Examinations for Agricultural Scholarships in the second week in September.

THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, *i.e.*, three winter sessions of six months and three summers of three months, with the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £6 6s., or £12 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as

follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 64 beds; Richmond Hospital, 86 beds—total, 270 beds. These hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are large ophthalmic, aural, throat, and gynæcological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoins these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, F.R.C.S., 47, Fitzwilliam Square, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Two House Surgeons are elected annually and three resident pupils half-yearly. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15, St. Stephen's Green North.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital has recently been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with the most modern surgical requirements. A Röntgen-ray and light treatment of lupus department has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Mr. G. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.
